P R E F A C E.

IN undertaking this work the author was more influenced by an anxious desire to extend the views of medical science generally, and of his own profession in particular, and a wish to draw the attention of agriculturists and veterinary surgeons to a too much neglected and undervalued class of animals, than by the hope of materially increasing the amount of knowledge already possessed.

It has been his task to collect all the various brief and cursory notices which have been accorded to swine by ancient as well as modern agricultural and medical writers; to select those which were valuable and worthy of record; and then, by weaving them into the groundwork of his own ideas and experience, to bring the before scattered rays into one focus, so that the eye of science may be attracted towards this hitherto neglected branch, and, from contemplating, may be led to study it; and practical men may be induced to aid, by their experience, in elucidating a subject which is as yet so little understood.

In short, he has endeavoured to act as a pioneer, to lead the way to, and break up, a new and fertile spot; one that will amply reward the labours of those whom he hopes to induce by his example to bestow some little of their care upon it.

Many talented and valued friends have kindly assisted him by hints and information; to them he tenders his sincere thanks. Should it be deemed that he has succeeded in throwing some

portion of light, faint though it may be, on the management and diseases of animals whose value is becoming more and more acknowledged every year, he will consider his labours amply rewarded.

WILLIAM YOUATT.

December, 1846.

Editor's Note.—The sudden death of the talented and lamented author having deprived this work of the benefit of his supervision through the press, the Editor has to request the indulgence of the public for any errors which may accidentally have crept in.

THE PIG.

CHAPTER I.

Zoological definition of the Pig—The order Pachydermata—The Peccary—The Babiroussa—The Phaco-choeres—The Capibara—Various animals have been called by the name of Hog.

THE HOG (*Suidae Sus* of the ancients and Linnæus,) according to Cuvier, belongs to “the class MAMMALIA, order PACHYDERMATA, genus SUIDAE or SUS, having on each foot two large principal toes shod with stout hoofs, and two lateral toes much shorter and scarcely touching the earth; the incisors variable in number, the lower incisors all levelled forwards; the canines projected from the mouth and recurved upwards; the muzzle terminated by a truncated snout fitted for turning up the ground; the stomach but little divided; the body square and thick, and more or less covered with bristles and hairs; the neck strong and muscular; the legs short and stout.”* All this species feed on plants, and especially on roots, which their snout or trunk enables them to grub out of the earth; they will devour animal substances, but rarely hunt or destroy animals for the purpose of devouring them. They are thick skinned; said to be obtuse in most of their faculties, excepting in the olfactory and oral senses; voracious; bold in defending themselves; and delight in humid and shady places.

To this order belong the elephant, the rhinoceros, the hippopotamus, &c., the general characteristics of all of which are very similar.

Under the generic term SUIDAE or SUS many zoologists have included, besides the true hog as it exists in a wild or tame state in Europe, Asia, and Africa, the peccary, the babiroussa, the phaco-choere, and the capibara; we will, therefore, slightly glance at each of these varieties before proceeding to the actual subject of the present work.

THE PECCARY.—This appears to be the nearest approach to swine among the animals indigenous to the New World; and the Collared Peccary (*Dicotyles torquatus*) and the White-lipped Peccary (*Dicotyles labiatus*) actually do at first sight appear to bear a very close resemblance to the common hog, but a more careful examination soon enables us to detect material differences. The head is thicker and shorter, the body not so bulky, the legs shorter, the hoofs longer, the ears shorter, and the tail is supplied by a slight, and at a cursory glance almost imperceptible, protuberance. But the great difference arises from a

* Cuvier's Animal Kingdom, vol. iii.

small gland on the back, which, although partially concealed by the hair, is nevertheless evident, and hence it is that the term *Dicotyles*, which signifies a double navel, has been given to this species. This gland secretes a fluid which is emitted in great abundance whenever the animal is irritated, and gives out a very strong odour, pronounced as fetid and disagreeable by some authors, and by others compared to musk.

Cuvier remarks that the external toe on the hind feet is wanting in the peccary. The body is of a grayish hue, and thickly covered with strong coarse bristles, stiff enough to penetrate a tolerably firm substance, and shaded black and white. These are longest on the back, where some will be found measuring four or five inches; they become gradually shorter and shorter on the sides, and disappear altogether on the belly, which is nearly bare. On the head is a large tuft of black bristles. The eyes and snout are small, and the ears erect.

This animal is found in vast numbers in Paraguay and Guiana, and has been termed by some writers the Mexican hog. It has nearly the same habits and tastes as the common hog; feeds on seeds and roots; digs with its snout; expresses its emotions by grunts; is fierce in defence of its young; very prolific; and the flesh is similar to ordinary pork, but harder, less sweet and juicy, and not so fat.

The peccary may be tamed if taken when young, and will attach itself to those who are kind to it, and to dogs and other animals; is fond of being caressed and scratched, and will answer to its keeper's voice.

The European hog when transplanted to the wilds of America will herd with the peccaries, but is never known to breed with them; the two races, although resembling each other in certain points, are, and remain distinct. The hog is the larger, stronger, and more useful animal, and will thrive in almost any part of the world: the peccary is smaller, weaker, and cannot be made to live in a foreign climate without very great care and attention.

The BABIROUSSA (*sus baby-roussa*), or Hog-deer, or, as it has been termed by some foreign authors, the Indian hog, is chiefly found in the Moluccas, Sumatra, Java, and other islands of the Indian Archipelago.

This animal stands higher than the common hog; its legs are long and slender; its skin thin and scantily furnished with short woolly hair of a reddish brown on the back, and lighter and more inclined to fawn-colour on the belly. It is chiefly remarkable for the strange position of its upper tusks, which come through the skin of the muzzle and curve backwards almost like horns, until they nearly or quite touch the skin again; they are sometimes as much as nine inches in length and five in circumference. Pliny evidently alludes to this animal when he says that wild boars are found in India which have two horns on the face, similar to those of a heifer, and tusks like the common wild boars.*

There are all the family characteristics of the hog in this animal; the heavy awkward gait, thick neck, small eyes, head terminated by a snout, and grunting voice; it feeds, too, on roots, plants, and leaves, and some say shell-fish; but some authors assert that it does not grub roots out of the ground like most of the swinish varieties. Sparrman informs us

* Pliny, b. 8, chap. lii.

that the natives would rather attack a lion than this animal, for it comes rushing on a man swift as an arrow, and, throwing him down, snaps his legs in two and rips his belly up in a moment.*

The flesh of the babiroussa is very fine eating, and the Malays melt down the fat to use instead of butter and oil.

Cuvier has given an account of a pair that were at the Menagerie at Paris, the female of which was much younger and more active than the male; he was old and fat, and only ate, drank, and slept. When the male retired to rest the female would cover him completely over with straw or litter, and creep in after him, so that both were concealed from sight. The specimen at the Zoological Gardens in the Regent's Park used to cover himself up with straw in the same way.

THE PHACO-CHOERES.—There are two recognised species of this variety of the hog family, the one found in Guinea and the interior of the Cape, and spoken of by various writers as the Wark-hog, and the other first seen in Kordofan and afterwards in several parts of Abyssinia, and referred to by Ælian as the hog with four horns. Of the habits of these creatures little is known, save that they are inhabitants of forests, and their food is vegetable.

They are remarkable for the two warts or fleshy excrescences which disfigure the face on either side; the eyes are small; a bristly mane of a pale brown colour rises between the ears and extends itself along the back, many of the hairs of which are from eight to ten inches in length; the body is bare; the tail thin and terminated by a tuft of hair; and the tusks very large and powerful.

THE CAPIBARA—is an animal which is often classed by modern zoologists among the Cavies; it also resembles a two-year old hog in shape and colour, but its head is longer, its eyes larger, and its nose cleft like the lip of a rabbit, instead of being round. It has thick coarse whiskers, a narrow mouth, and no tusks. The front hoofs are divided into four parts, and the back ones into three, and these divisions or toes are connected together by skin, and thus in a manner webbed, and adapted for swimming; indeed so much does it delight in the water that by some it has been called the water-hog. It lives upon fruit, corn, and sugar-canes, and eats all the fish it can catch. These animals associate in herds and seldom go out of their lair excepting in the night time, or quit the borders of some lake or river, for their short legs and strangely formed feet prevent them from running with any degree of speed, so their only safety is in the water, wherein they plunge on the least alarm.

If taken young this animal may easily be tamed, and is capable of great attachment. We are informed that its flesh is tender, juicy, and fat, but has a fishy flavour; the head is, however, said to be excellent.

Cuvier refuses to admit this last-mentioned animal among the **PA-CHYDERMATA**, but places it in the order **RODENTIA**, genus *Cavia*.

The animal, too, so well known to us by the name of Guinea-pig, or among the French as the *Cochon d'Inde*, he also classes among the **Rodentia**.†

The name Hog has been given by different nations to various animals which have no affinity whatever with the actual family *Sus*: thus the

* Sparrman's Voyage, vol. ii.

† Cuvier's Animal Kingdom.

Spaniards call the *tatous*, hogs in armour; the Hollanders term the *porcupine*, the iron-hog; the *porpoise* has frequently been designated the sea-hog; and Aristotle speaks of a hog-ape, which has been since supposed to refer to one of the baboon tribe; while among our common animals we have the hedge-hog. This has led to much confusion and misapprehension; but the genus *Suidae* or *Sus* is now very generally allowed to apply only to the actual swine as they exist in a wild or domesticated state throughout the greater part of the known world.

CHAPTER II.

Derivation of the term Hog—The Hog was greatly esteemed by the Romans—Worshipped by some of the ancients—Swine's flesh prohibited by the law of Moses—By that of Mohammed—Despised by the Egyptians.

THE term Hog is stated by Carpenter to be derived from the Hebrew word חזיר, by which this animal was designated among the Hebrews, a word derived from חזר, to *encompass* or *surround*, suggested by the round figure of this animal when in his fat and most natural state. Bochart and Schultens, however, are more inclined to refer the Hebrew noun to the Arabic sense of the verb, viz., to *have narrow eyes*, and there is much of probability in their supposition. In some respects swine seem to form an intermediate link between the whole-footed and cloven-footed animals, and in others to occupy the same ground between the cloven-footed and the digitative; but look on them in what point of view we may, these animals present various peculiar characteristics, and are of vast importance as affording the means of sustenance to millions of human beings in all parts of the world. The hog is a perfect cosmopolite, adapting itself to almost every climate; increasing rapidly, being more prolific than any other domestic animal, with the exception of the rabbit; easily susceptible of improvement, and quickly attaining to maturity.

As far back as the records of history enable us to go, the hog appears to have been known, and his flesh made use of as food. 1491 years before Christ, Moses gave those laws to the Israelites which have occasioned so much discussion, and given rise to the many opinions which we shall presently have to speak of; and it is quite evident that had not pork then been the prevailing food of that nation, such stringent commandments and prohibitions would not have been necessary. The various allusions to this kind of meat, which occur again and again in the writings of the old Greek authors, plainly testify the esteem in which it was held among this nation, and it appears that the Romans actually made the art of breeding, rearing, and fattening pigs a study, which they designated *Porculatio*. Every art was put in practice to impart a finer and more delicate flavour to the flesh: the poor animals were fed, and crammed, and tortured to death in various ways, many of them too horrible to be described, in order to gratify the epicurism and gluttony of this people. Pliny informs us that they fed swine on dried figs, and drenched them to repletion with honeyed wine, in order to produce a diseased and monstrous-sized liver. The *Porcus Trojanus*,

so called in allusion to the Trojan horse, was a very celebrated dish, and one that eventually became so extravagantly expensive that a sumptuary law was passed respecting it. This dish consisted in a whole hog, with the entrails drawn out, and the inside stuffed with thrushes, larks, beccaficoes, oysters, nightingales, and delicacies of every kind, and the whole bathed in wine and rich gravies. Another great dish was a hog served whole, the one side roasted and the other boiled.

Varro states that the Gauls produced the largest and finest swine's flesh that was brought into Italy; and, according to Strabo, in the reign of Augustus they supplied Rome and nearly all Italy with Gammons, hog-puddings, hams, and sausages. This nation and the Spaniards appear to have kept immense droves of swine, but scarcely any other kind of live stock; and various authors mention swine as forming a part of the live stock of most Roman farms.

In fact the hog was held in very high esteem among the early nations of Europe, and some of the ancients have even paid it divine honours. In the island of Crete it was regarded as sacred. This animal was always sacrificed to Ceres at the beginning of harvest, and to Bacchus at the commencement of the vintage, by the Greeks; probably, it has been suggested, "because this animal is equally hostile to the growing corn and the ripening grape."

The Jews, the Egyptians, and the followers of Mohammed, alone appear to have abstained from it. To the former nation it is expressly forbidden by the laws of Moses. Leviticus xi. 7, says: "And the swine, though he divide the hoof, and be cloven-footed, yet he cheweth not the cud; he is unclean unto you." Mohammed probably founded his prohibition on this one, or was induced, by the prejudices of his followers, to make it. Numerous theories have been advanced by different authors to account for this remarkable prohibition uttered by Moses against a species of food generally so wholesome and nutritious as the flesh of the hog, Maimonides says: "The principal reason why the law prohibited the swine was, because of their extreme filthiness, and their eating so many impurities; for it is well known with what care and precision the law forbids all filthiness and dirt, even in the fields and in the camp, not to mention in the cities. Now had swine been permitted, the public places, and streets, and houses, would have been made nuisances."*

Tacitus states that the Jews abstained from it in consequence of a leprosy by which they had formerly severely suffered, and to which the hog is very subject. And several other writers concur in this view, stating that it was on account of the flesh being strong, oleaginous, difficult of digestion, and liable to produce cutaneous diseases, that it was forbidden. Michaëlis observes, that throughout the whole climate under which Palestine is situated, leprosy is an endemic disease; and the Israelites being overrun with it at the period of their quitting Egypt, Moses found it necessary to enact a variety of laws respecting it, and the prohibiting the use of swine was one of these.†

M. Sonnini states that in Egypt, Syria, and even the southern parts of Greece, swine's flesh, although white and delicate, is so flabby and

* More Nevochim, part iii. c. 8.

† Commentaries on the Law of Moses, Art. 203. vol. ii.

sur-charged with fat, as to disagree with the strongest stomachs,* and this will account for its prohibition by the priests and legislators of hot climates, such an abstinence being absolutely necessary to health beneath the burning suns of Egypt and Arabia. "The Egyptians," he says, "were only allowed to eat pork once a year, on the feast-day of the moon, and then they sacrificed a number of these animals to that planet. If at any other time an Egyptian even touched a hog, he was obliged to plunge into the Nile, clothes and all, to purify himself. The swineherds formed an isolated race, outcasts from society, forbidden to enter a temple, or intermarry with other families."† Hence it probably is that, in the beautiful parable of the Prodigal Son, this unhappy young man is represented as being reduced to the office of a swineherd, that being considered as the lowest possible degradation.

Others are of opinion that this and many other of the prohibitions and ordinances established by Moses were solely for the purpose of distinguishing the Jews from other nations, and making them what they are to this day in all countries and under all climates, "a peculiar people." Others, again, assert that it was with a view to correct their gross and glutinous habits that none but the simplest and mildest kinds of animal food were permitted to the Jews. And, lastly, another maintains that the swine was thus declared an abomination in the sight of God as a lesson to the Jews to abstain from the sensual and disgusting habits to which this animal is given.‡

This aversion to swine has descended to the Jews, Egyptians, and followers of Mohammed of modern times. The Copts rear no pigs, indeed this animal is scarcely known in most of the cities of Lower Egypt; and the poorest Jew would sooner starve than touch a morsel of this forbidden food, even though the presumed cause of the prohibition has long ceased to exist, and he is removed to colder climes, where pork is both wholesome and nutritious.

By the precepts, warnings, and threatenings of the prophets, we read that, so great was the detestation excited in the minds of the Jewish nation against this animal, that they would not even pollute their lips by pronouncing its name, but always alluded to it as "that beast," "that thing;" and we read in the history of the Maccabees, that Eleazer, a principal scribe, being compelled by Antiochus Epiphanes to open his mouth and receive swine's flesh, spit it forth, and went of his accord to the torment, choosing rather to suffer death than break the divine law and offend his nation.§

And yet it is well known that immense numbers of swine were reared in the country of the Jews, probably for the purpose of gain, and in order to supply strangers and the neighbouring idolaters; and it has been supposed,|| that it was in order to punish this violation of the Divine commandments that our Saviour permitted the herd of swine to be affected with that sudden disorder which caused them to rush headlong into the lake of Genesareth.¶

* Plutarch (*de Iside*) affirms that those who drank the milk of swine became blotchy and leprous.

CHAPTER III.

The early history of Swine—Legendary and authentic records respecting the keeping of them in England—Ancient Welsh laws relative to Swine—The forests of England—Swineherds—Their mode of managing their herds—Calabrian Swineherds—Horn used to assemble the grunting troop—The Schwein-General—Herds of Swine kept in France—Value of Pigs—Some vindication of them—Anecdotes proving their teachability—Sagacity of a Pig—Some demonstrations of Memory in one—Attachment to individuals—Swine not innately filthy animals—They are possessed of more docility than they usually have credit for—Their exquisite sense of smell—Pigs said to foretell rain and wind.

In our own country the keeping of large herds of swine can be traced back to 863 years before Christ, at least if any reliance may be placed on the ancient and legendary history of Bath, for there it is recorded that, about 2709 years ago, a numerous herd of swine was kept by a British prince in the neighbourhood of Bath, to whom we owe the discovery of the medicinal qualities of the hot springs there. "Baldred, eldest son of Lord Hudibras (then King of Britain,) it is said, having spent eleven years at Athens in study, came home leprous, and was in consequence confined to prevent infection. Having effected his escape, however, he went very remote from his father's court, into an untravelled part of the country, and offered his services in any common employment. He entered into service at Learwick, a small village three miles from Bath, where his business was to take care of pigs, which he was to drive from place to place for their advantage in feeding upon acorns, haws, &c. While at his usual employment one morning, a part of the drove of swine, as if seized with a frenzy, ran down the side of the hill into an elder-moor, till they reached the spot of ground where the hot springs of Bath now boil up, and from thence returned, covered with black mud. The prince being of a thoughtful turn, was very desirous to find out the reason why pigs that wallowed in the mire in summer to cool themselves, should do the same in winter; at length he perceived a steam arise from the place where they had wallowed, and making his way to it, found it warm. Having thus satisfied himself that it was for the benefit of the heat that the pigs resorted hither, he observed, that after awhile they became whole and smooth from their scabs and eruptions by often wallowing in this mud. Upon this he considered within himself why he should not receive the same benefit by the like means. He tried the experiment with success, and finding himself cured of his leprosy, declared who he was. His master, though incredulous at first, being at last persuaded to believe him, went with him to court, where he was owned; and upon succeeding to his father, he erected the baths. In one of these baths there is at the present time a statute of King Baldred, which was erected in 1699, under which is the following inscription on copper: "Baldred, son of Lord Hudibras, eighth King of the Britons from Brute, a great philosopher and mathematician, bred at Athens, and recorded the first discoverer and founder of these baths, 863 years before Christ."

In Greece and the neighbouring islands it would seem that swine were also common at even an earlier period, and were kept in large droves by swineherds; for we read in Homer's *Odyssey*, which is supposed to have been written upwards of 900 years B.C., that Ulysses, on

his return from the Trojan war, first sought the dwelling of Eumæus, his faithful servant, and the keeper of his swine: and that office must then have been held in higher esteem than it subsequently became, or was in other countries, or it would not have been performed by that wise and good old man, himself a descendant of princes.

"But he, deep-musing, o'er the mountains stray'd,
Thro' mazy thickets of the woodland shade,
And cavern'd ways, the shaggy coast along,
With cliffs and nodding forests overhung.
Eumæus at his sylvan lodge he sought,
A faithful servant and without a fault.
Ulysses found him busied, as he sat,
Before the threshold of his rustic gate;
Around the mansion in a circle shone
A rural portico of rugged stone;
(In absence of his lord, with honest toil
His own industrious hands had raised the pile)—
'The wall was stone from neighbouring quarries borge,
Encircled with a fence of native thorn,
And strong with pales, by many a weary stroke
Of stubborn labour, hewn from heart of oak;
Frequent and thick. Within the space were reared
Twelve ample cells, the lodgments of his herd.
Full fifty pregnant females each contain'd,
The males without (a smaller race) remained;
Doomed to supply the Suitors' wasteful feast,
A stock by daily luxury decreas'd,
Now scarce four hundred left. Those to defend,
Four savage dogs, a watchful guard, attend.
Here sat Eumæus, and his cares apply'd
To form strong buskins of well-seasoned hide.
Of four assistants who his labour share,
Three now were absent on the rural care;
The fourth drove victims to the suitor train;
But he of ancient faith a simple swain,
Sigh'd while he furnish'd the luxurious board,
And weary'd heaven with wishes for his lord."—xiv. 1-30.

The rude tables of the ancient Britons were chiefly supplied from their herds of swine, and the flesh of these animals furnished them with a great variety of dishes.*

Sharon Turner, in his History of the Anglo-Saxons, while enumerating their live stock, states they had "great abundance of swine;" and adds, that although horned cattle are occasionally mentioned in grants, wills, and exchanges of property, swine are most frequently spoken of.

The country then abounded with woods and forests, and these are seldom particularized without some mention being made of the swine fed in them. These animals appear in fact to have constituted a considerable item in the wealth of an individual, for legacies of them often occur in wills. Thus Alfred, a nobleman, bequeaths to his relatives a hide of land with one hundred swine, and directs that another hundred shall be given for masses for the benefit of his soul; and to his daughters he leaves two thousand. So Elfhelm left land to St. Peter's at Westminster on the express condition that they should feed a herd of two hundred swine for the use of his wife.†

In the original Domesday-Book for Hampshire, where an estimate of the value of the lands and forests belonging to the king, the monasteries, the hundreds, and other divisions is given, the number of hogs which can be fed on each separate portion is invariably specified.‡

† Sharon Turner's Hist. of Anglo-Saxons, vol. iv.

‡ Warner's History of Hampshire.

In the oldest of the Welsh Triads (which treat of the events of Britain in general,) we find evidence of the early domestication of swine, for one of these contains a recital of the actions of three powerful swineherds in the Isle of Britain, "over whom it was not possible to prevail or gain," and who restored the swine to their owners with increase. Some of the fabulous narrations blended with the history of these swineherds have been attributed by antiquarians to a period antecedent to Christianity.

In the laws of Howel, or (as some write it) Hoel Dha, there is a chapter on the value of animals, in which it is stated "that the price of a little pig from the time it is born until it grows to burrow, is one penny; when it ceases sucking, which is at the end of three months, it is worth two pence; from that time it goes to the wood with the swine, and it is considered as a swine, and its value is four pence; from the Feast of St. John unto the 1st day of January, its value is fifteen pence; from the 1st of January unto the Feast of St. John, its value is twenty-four pence; and from that time forward its value shall be thirty pence, the same as its mother."

"The qualities of a sow are, that she breeds pigs and do not devour her young ones. The seller must also warrant her sound against the quinsy for three days and nights after she is sold. If she should not possess these qualities, one-third of her price must be returned. The value of a boar is equal to the value of three sows."*

There are several enactments in these same laws of Howel Dha, which regulate the compensation for corn spoiled or damaged by the trespassing of swine; and it is stated in that part of the code, that "little pigs, from the time they turn up the cow-dung with their noses, are subject to the same law as their mothers." The following seems more singular than just: "If swine enter a house and scatter about the fire, so as to set the house on fire, and the swine escape, let the owner of the swine pay for the act. If the swine be burnt, then both house and swine are equal, for both are stupid; therefore as both have equally suffered according to law, there is nothing to be redressed, but the injury of the one must be set against the injury of the other." This appears rather hard, seeing that the swine came to the fire, and not the fire to the swine.

In a paper by Dr. Hibbert,† entitled "Illustrations of the Customs of a Manor in the North of England," &c., there is the following notice regarding swine, derived from an ancient court-roll of the manor of Ashton-under-Lyne, in Lancashire, dated A. D. 1422.

"Attached to these ordinances was a covenant between Sir John of Assheton and his tenants, relative to the keeping of swine. These animals were allowed to range in the demesnes of the town from the latter end of August until sowing-time, provided that they were properly ringed, and did no harm; in default whereof the owner was to loose him to the lord four pence, or by this sum redeem the animal from poundage. The brewer who brewed to sell, and the miller, were allowed to keep three swine; the tenants who had land in the fields, two swine; and he who held no land might have one swine."

In a chapter on "The King's Entertainment from the Manors," it is

* Hoel Dha, *Leges, Wallicæ*, 41.

† Transactions of the Antiquarian Society of Scotland, vol. iii.

stated that among various rents which vassal manors must grant the king is a three-year old swine in winter. And among the articles which form the king's entertainment from a free manor in winter, are enumerated "a three-years old swine and a fitch of bacon salted, being three fingers in thickness."

The British forests, which formerly occupied the greater part of England, were peopled by the swinish multitude. Hertfordshire was nearly covered with wood and forest land; Buckinghamshire boasted its magnificent Bern Wood; Hampshire, its extensive New Forest; nor were the other counties destitute of these sylvan retreats, which have latterly vanished before the axe of the woodman and the industry of the husbandman. The "Merrie green wood" has given place to pasture and cultivated fields; shepherds now feed their flocks where the swineherd formerly drove his grunting troop; and waving corn displays its golden harvest where once acorns and—

"the falling mast
For greedy swine provides a rich repast."

In 1646 Norwood in Surrey is described as containing 830 acres from which the inhabitants of Croydon "have herbage for all kinds of cattle, and mastage for swine without stint."

The right of forest borderers to fatten their swine in the various forests, formerly royal property, is very ancient, being evidently anterior to the Conquest. At first a small tax or fee was paid by those holding this right; but whether this went to the crown, or consisted in a certain gratuity to the forest ranger or the swineherd, is no where specified in the records. This privilege, like all others, was greatly abused; for many of the keepers availed themselves of it, and kept large herds of swine which they suffered to run the forests during the whole of the year, doing exceeding damage to the timber as well as to the land.

The actual period for which it was lawful to turn swine into the royal woods and forests for *masting*, was from fifteen days before Michaelmas to forty days afterwards,* and this was termed the pawnage month.

The method of treating hogs at this season of migration, and reducing a large herd of these unmanageable brutes to order and obedience, is thus graphically described by Gilpin:—

"The first step the swineherd takes is to seek out some close sheltered part of the forest where there is a conveniency of water, and plenty of oak or beech mast; the former of which he prefers when he can have it in abundance.

"He next fixes on some spreading tree, round the bole of which he wattles a slight circular fence of the dimensions he wants, and, covering it roughly with boughs and sods, he fills it plentifully with straw or fern.

"Having made this preparation, he collects his colony among the farmers, and will get together perhaps a herd of five or six hundred hogs. Having driven them to their destined habitation, he gives a plentiful supper of acorns or of beech-mast which he had already provided, sounding his horn during the repast. He then turns them into the litter, where, after a long journey and a hearty meal, they sleep soundly.

* Manwood's Forest Law.

"On the next morning he suffers them to look around, shows them the pool or stream where they may occasionally drink, leaves them to gather the offals of the last night's meal; gives them another plentiful repast under the neighbouring trees—that almost rain acorns upon them—for a considerable time to the sound of his horn, and then sends them once more to sleep.

"On the following day he is perhaps at the pains of procuring them another meal, with music playing as before. He then leaves them a little more to themselves, keeping his eye, however, on them about evening; when their bellies are full, they seldom wander far from home, but commonly retire orderly and early to bed.

"After this he throws his sty open, and leaves them to cater for themselves, and henceforward has little more trouble with them during the whole time of their migration.

"Now and then, in calm weather, when mast falls sparingly, he perhaps calls them together by the music of his horn to a gratuitous meal; but they require very little further teaching, but return home regularly every evening, although they sometimes stray two or three miles from their sty. There are always experienced leaders among the herd, who, having led this rambling life before, are competent to instruct their juniors in the method of it. By this management the herd is carried home to its owners in such a condition that a little dry meat will soon fatten them.

"I would not, however, have it supposed that all the swineherds in the forest can manage their colonies with such exactness. The hog is commonly supposed to be an obstinate, headstrong beast, and he may perhaps have a degree of positiveness in his temper; but if properly managed he is, or may be made, an orderly docile animal. When your meanings are fair, and friendly, and intelligible, he may be led with a straw; nor is he without his social feelings, when he is at liberty to indulge them.

"During his migrations in the forest, it is commonly observed that of whatever number the herd consists before setting forth on their daily excursions, they generally separate themselves into parties, and may thus be met with in those friendly groups, some earlier and some later, according as they have been more or less fortunate in the pursuits of the day.

"Beside the hogs thus led out in the mast-season to fatten, there are others, the property of forest-keepers, who spend the whole year in similar societies.

"After the mast-season is over, the indigenous forest hog depends chiefly for his livelihood on the roots of fern, and he would find this food very nourishing if he could have it in abundance; but he is obliged to procure it by so laborious an operation, that his meals are rarely accompanied by satiety. He continues, however, by great industry, to obtain a tolerable subsistence through the winter, except in frosty weather; and he must then perish if he does not, in some degree, experience his master's care.

"Besides these stationary hogs, there are others in some of the desolate parts of the forest that are bred wild, and left to themselves without any settled habitation, and as they cost nothing in their food, their

owners are content with the precarious profits of such as they are able to reclaim."*

Our readers must forgive us if we add yet another view of this picture, given in the truthful and simply descriptive lines of our rural poet, Bloomfield :—

"From oak to oak they run with eager haste,
And wrangling share the first delicious taste
Of fallen acorns; yet but thinly found
Till the strong gale has shook them to the ground.
It comes, and roaring woods obedient wave;
Their home well pleased the joint adventurers leave.
The trudging sow leads forth her numerous young,
Playful, and white, and clean, the briars among;
Till briars and thorns increasing force them round,
Where last year's mouldering leaves bestrew the ground,
And o'er their heads, loud lash'd by furious squalls,
Bright from their cups the rattling treasure falls.
Hot, thirsty food; whence doubly sweet and cool
The welcome margin of some rush-grown pool."

Nor was the practice of feeding swine in herds, and accustoming them to assemble at the sound of the horn, peculiar to this country. In Calabria they are grazed in herds, and the keeper uses a kind of bagpipe, the tones of which, when the period arrives for their being driven home, quickly collects the scattered groups from every part. In Tuscany it is the same.

Barna Goge, in commending the use of the horn to all keepers of swine, gives the following ludicrous anecdote:—"Certain pirates, who seem not well to have learned their business, since they were unable to swim, landed on the coast of Tuscany, and carried off a number of swine to their boats, and were just paddling off when the swineherd, missing some of his charges, winded his horn. At the well-known sound up started all the grunTERS *una et viva voce*, and crowding to one side of the boat upset it, and swam ashore to their keeper, leaving the unfortunate thieves floundering in the sea."

In Germany almost every village has its swineherd, who at break of day goes from house to house collecting his noisy troop, blowing his still more noisy cow-horn, and cracking his clumsy whip, until the place echoes with the din. The following very amusing account of that important personage, the *Schwein-General*, has lately been given in a popular work :—

"Every morning, at half-past five o'clock, I hear, as I am dressing, the sudden blast of an immense long wooden horn, from which always proceed the same four notes. I have got quite accustomed to this wild *réveille*, and the vibration has scarcely subsided, it is still ringing among the distant hills, when, leisurely proceeding from almost every door in the street, behold a pig! Some, from their jaded, care-worn appearance, are evidently leaving behind them a numerous litter; others are great, tall, monastic, melancholy-looking animals, which seem to have no other object left in this wretched world than to become bacon; while others are thin, tiny, light-hearted, brisk, petulant piglings, with the world and all its loves and sorrows before them. Of their own accord these creatures proceed down the street to join the herdsman, who occasionally continues to repeat the sorrowful blast from his horn.

"Gregarious, or naturally fond of society, with one curl in their tails,

* Gilpin's Forest Scenery.

and with their noses almost touching the ground, the pigs trot on grunting to themselves and to their comrades, halting only whenever they come to anything they can manage to swallow.

"I have observed that the old ones pass all the carcasses which, trailing to the ground, are hanging before the butchers' shops, as if they were on a sort of *parole d'honneur* not to touch them; the middle-aged ones wistfully eye the meat, yet jog on also; while the piglings, who (so like mankind) have more appetite than judgment, can rarely resist taking a nibble. Yet no sooner does the dead calf begin again to move, than from the window immediately above out pops the head of a butcher, who, drinking his coffee whip in hand, inflicts a prompt punishment, sounding quite equal to the offence.

"As I have stated, the pigs, generally speaking, proceed of their own accord; but shortly after they have passed, there comes down our street a little bare-headed, bare-footed, stunted drab of a child about eleven years old—fibbertigibbet sort of creature, which in a drawing one would express by a couple of blots, the small one for her head, and the other for her body, while, streaming from the latter, there would be a long line ending in a flourish to express the immense whip which the child carries in its hand. This little goblin page, the whipper-in, attendant, or aide-de-camp of the old pig-driver, facetiously called at Langen-Schwalbach the 'Schwein-General,' is a being no one looks at, and who looks at nobody. But such a pair of eyes for a pig have seldom, perhaps, beamed from human sockets! The little intelligent urchin knows every house from which a pig ought to have proceeded: she can tell by the door being open or shut, or even by footmarks, whether the creature has joined the herd, or whether, having overslept itself, it is still snoring in its sty. A single glance determines whether she shall pass a yard, or enter it; and if a pig, from indolence or greediness, be loitering on the road, the sting of the wasp cannot be sharper or more spiteful than the cut she gives it. As soon as she has finished with our street, she joins her general in the main road; the herd slowly proceed down the town.

"As I followed them this morning, they really appeared to have no hams at all; their bodies were as flat as if they had been squeezed in a vice, and when they turned sideways, their long sharp noses and tucked-up bellies gave to their profile the appearance of starved grayhounds.

"Besides the little girl who brought up the rear, the herd was preceded by a boy of about fourteen, whose duty it was not to let the foremost, the most enterprising, or, in other words, the most empty pig, advance too fast. In the middle of the drove, surrounded like a shepherd by his flock, slowly stalked the 'Schwein-General,' a wan spectre-looking old man, worn out, or nearly so, by the arduous and every-day duty of conducting against their wills a gang of exactly the most obstinate animals in creation. A single glance at his jaundiced, ill-natured countenance, was sufficient to satisfy one that his temper had been soured by the vexatious contrarieties and 'untoward events' it had met with. In his left hand he held a staff to help himself onwards, while round his right shoulder hung one of those terrific whips which must be seen to be imagined. At the end of a short handle, turning upon a swivel, there was a lash about nine feet long, formed like the vertebrae of a snake, each joint being an iron ring, which, decreasing in size, was

closely connected with its neighbour by a band of hard greasy leather. The pliability, the weight, and the force of this iron whip, rendered it an argument which the obstinacy even of the pig was unable to resist; yet, as the old man proceeded down the town, he endeavoured to speak kindly to the herd, and as the bulk of them preceded him, he occasionally exclaimed in a low, hollow, worn-out tone of encouragement, 'Nina! Anina!' (drawing, of course, very long on the last syllable.)

"If any little savoury morsel caused a contention, stoppage, or constipation on the march, the old fellow slowly unwound his dreadful whip, and by merely whirling it round his head, like reading the Riot Act, generally succeeded in dispersing the crowd; but if they neglected this solemn warning—if their stomachs proved stronger than their judgments, and if the group of greedy pigs still continued to stagnate, 'Arriff!' the old fellow exclaimed; and rushing forwards, the lash whirling round his head, he inflicted with strength which no one would have fancied he possessed, a smack that seemed absolutely to electrify the leader. As lightning shoots across the heavens, I observed the culprit fly forwards, and for many yards continuing to sidle towards the left; it was quite evident that the thorn was still smarting in his side, and no wonder, poor fellow! for the blow he received would almost have cut a piece out of a door.

"As soon as the herd got out of the town, they began gradually to ascend the rocky, barren mountain which appeared towering above them, and then the labours of the *Schwein-General* and his staff became greater than ever; for as the animals from their solid column began to extend or deploy themselves into line, it was necessary constantly to ascend and descend the slippery hill, in order to outflank them. 'Arriff!' cried the old man, striding after one of his rebellious subjects; 'Arriff!' in a shrill tone of voice was re-echoed by the lad, as he ran after another. However, in due time the drove reached the ground which was devoted for that day's exercise, the whole mountain being thus taken in regular succession.

"The *Schwein-General* now halted, and the pigs being no longer called upon to advance, but left entirely to their own notions, I became exceedingly attentive in observing them.

"No wonder, poor reflecting creatures! that they had come unwillingly to such a spot, for there appeared literally nothing for them to eat but hot stones and dust; however, making the best of the bargain, they all very vigorously set themselves to work. Looking up the bill, they dexterously began to lift up with their snouts the largest of the loose stones, and then grubbing their noses into the cool ground. I watched their proceedings for a very long time. Their tough wet snouts seemed to be sensible of the quality of every thing they touched, and thus out of the apparently barren ground they managed to get fibres of roots, to say nothing of worms, beetles, or any other travelling insects they met with. As they slowly advanced working up the hill, their ears most philosophically shading their eyes from the hot sun, I could not help feeling how little we appreciate the delicacy of several of their senses, and the extreme acuteness of their instinct.

"There exists, perhaps, in creation no animal which has less justice and more injustice done to him than the pig. Gifted with every faculty of supplying himself, and of providing even against the approaching

storm, which no creature is better capable of foretelling than a pig, we begin by putting an iron ring through the cartilage of his nose; and having thus barbarously deprived him of the power of searching for and analyzing his food, we generally condemn him for the rest of his life to the solitary confinement of a sty.

"While his faculties are still his own, only observe how, with a bark or snort, he starts if you approach him, and mark what shrewd intelligence there is in his bright twinkling little eye: but with pigs as with mankind, idleness is the root of all evil. The poor animal, finding that he has absolutely nothing to do, having no enjoyment, nothing to look forward to but the pail which feeds him, naturally most eagerly, or, as we accuse him, most greedily, greets its arrival. Having no natural business or diversion, nothing to occupy his brain, the whole powers of his system are directed to the digestion of a superabundance of food. To encourage this nature assists him with sleep, which, lulling his better faculties, leads his stomach to become the ruling power of his system—a tyrant that can bear no one's presence but his own. The poor pig thus treated gorges himself—sleeps—eats again—awakens in a fright—screams—struggles against the blue apron—screams fainter and fainter—turns up the whites of his little eyes—and dies!

"But to return to the *Schwein-General*, whom we left sitting with horn and whip by the side of the mountain.

"In this situation do the pigs remain every morning for four hours, enjoying little else but air and exercise. At about nine or ten o'clock they begin their march homewards, and nothing can form a greater contrast than their entry does to their exit from their native town.

"Their eager anxiety to get to the dinner trough that awaits them is almost ungovernable, and they no sooner reach the first houses of the town than a sort of '*saute qui peut*' motion takes place; away each of them starts towards his *dulce domum*; and it is really curious to stand still and watch how quickly they canter by, greedily grunting and snuffing, as if they could smell with their stomachs as well as their noses the savoury food which was awaiting them.

"At half-past four the same four notes of the same horn are heard again; the pigs once more assemble, once more tumble over the hot stones on the mountains, once more remain there for four hours, and in the evening once again return to their sties.

"Such is the life of the pigs, not only of Langen-Schwalbach, but those of every village throughout a great part of Germany: every day of their existence, summer and winter, is spent in the way I have described. The squad consists here of about 156, and for each pig the poor old *Schwein-General* receives 46 kreuzers (about 1s. 1d.) for six months' drilling of each recruit. The income therefore is about 26*l.* a-year, out of which he has to pay the board, lodging, and clothing of his two aides-de-camp; and when one considers how unremittingly these poor creatures have to contend with the gross appetites, sulky tempers, and pig-headed dispositions of the swinish multitude, surely not even the most niggardly reformer would wish to curtail his emoluments."*

In France, again, swine are kept in herds, and in many districts the

* Bubbles from the Brunnen.

feeding of them in the woods and forests (*le glandage*), under certain conditions and restrictions, has been a source of no inconsiderable emolument to the forester. Indeed to such an extent was it carried in certain localities, that it became an object of political economy. But of late years it has much diminished; the progress of agriculture is fast sweeping away those immense tracts of woodland country which formerly existed both in England and France, and with them depart the denizens of the forest, whether wild or tame, and the privileges and offices of foresters, rangers, &c.

Nature evidently designed the hog to fulfil many important functions in a forest country. By his burrowing after roots and such like, he turns up and destroys the larvæ of innumerable insects that would otherwise injure the trees as well as their fruit and roots. He greedily destroys the slug, the snail, the snake, and the adder, and thus not only rids the forest of these injurious and unpleasant inhabitants, but also makes them subservient to his own nourishment, and thus to the benefit of mankind. The fruits, too, which he eats, are such as would otherwise rot on the ground and be wasted, or yield nutriment to vermin; and his digging for earth-nuts, &c., loosens the soil and benefits the roots of the trees. Hence, under proper restrictions, the *oppanage* of hogs in forest-land may be regarded as eminently beneficial, and it is only the abuse of it which is to be feared. The celebrated German agriculturist, Thaër, does not, however, advocate the forest feeding of swine unless they are kept in the woods day and night and carefully sheltered; as he conceives that the bringing them home at night heats their blood, and nullifies the good effects of the day's feeding. He likewise considers that, although acorns produce good firm flesh, beech-mast makes unsound oily fat.

But if he is a useful animal in this public point of view, how much more so is he to individuals! Among the poorer classes of society how often is the pig their chief source of profit, of wealth, if we may so speak; in Ireland is this especially the case; there he is emphatically "*the gentleman what pays the rint*," better treated often than the peasant's own children. The small cost at which these animals can be reared and fattened, and their fecundity and wonderful powers of thriving under disadvantages, render them an actual blessing to many a poor cotter, who, with his little savings, buys a young and ill-conditioned pig, fattens it on all the refuse he can beg or spare, or collect, and sells it at a good profit, or occasionally, perhaps, kills it for the use of his family, who thus obtain an ample supply of cheap nutritious diet.

Were it not for this animal many of the labouring poor would scarcely be able to keep a roof over their heads, therefore we may with justice designate the hog "*the poor man's friend*."

With the exception of the rabbit, swine are the most prolific of all domesticated animals, and this is another argument in their favour. Nor does its value cease with its life; there is scarcely a portion of the pig that is not available for some useful purpose. The flesh takes the salt more kindly than that of any other animal, and, whether dried as bacon or salted down as pickled pork, forms an excellent and nutritious food, exceedingly valuable for all kinds of stores. The fat or lard is useful for numerous purposes—the housewife, the apothecary, and the

perfumer in particular know how to value it;—the head, the feet, and great part of the intestines, all are esteemed as delicacies. Brawn, that far-famed domestic preparation—which is evidently no recently invented dish, for at the marriage of Henry IV. in 1403, and of Henry V. in 1419, we find, among other records quoted by Strutt, that brawn and a kind of hashed pork formed the staple dishes—is made from the pig. The bristles, too, are another important item in the matters furnished by swine; they are used by brushmakers, and are necessary to the shoemaker, and some idea may be formed of the extent to which they form an article of use and of commerce, when we state that in the year 1828 alone, 1,748,921 lbs. of hog's bristles were imported into England from Russia and Prussia, each of which cannot have weighed less than two grains. From this we may fairly conjecture that 13,431,713,280 bristles were imported that year. As these are only taken from the top of the hog's back, each hog cannot be supposed to have supplied more than 7680, which, reckoning each bristle to weigh two grains, will be one pound. Thus in Russia and Prussia in 1828, 1,748,921 hogs and boars were killed to supply the consumption of bristles in England. The skin is formed into pocket-books, employed in the manufacture of saddles, and of various other things, and even the ears are eaten in pies.

It has been too much the custom to regard the hog as a stupid, brutal, rapacious, and filthy animal, grovelling and disgusting in all his habits; intractable and obstinate in temper. But may not much of these evil qualities be attributable to the life he leads? In a native state swine seem by no means destitute of natural affections; they are gregarious, assemble together in defence of each other, herd together for warmth, and appear to have feelings in common; no mother is more tender of her young than the sow, or more resolute in their defence. Besides, neglected as this animal has ever been by authors, there are not wanting records of many anecdotes illustrative of their sagacity, tractability, and susceptibility of affection. How often among the peasantry, where the pig is, in a manner of speaking, one of the family, may this animal be seen following his master from place to place, and grunting his recognition of his protectors.

The well authenticated account of the sow trained by Toomer, a gamekeeper to Sir Henry Mildmay, testifies to the teachability of these animals; and therefore, as it is our intention to defend them from many of the aspersions cast upon them, we will quote it.

“Toomer (formerly one of the king's keepers in the New Forest, and afterwards gamekeeper to Sir Henry Mildmay) actually broke a *black sow* to find game, and to back and stand. Slut was bred in, and was of that sort which maintain themselves in the New Forest without regular feeding, except when they have young, and then but for a few weeks, and was given, when about three months old, to be a breeding sow, by Mr. Thomas to Mr. Richard Toomer, both at that time keepers in the forest. From having no young she was not fed or taken much notice of, and, until about eighteen months old, was seldom observed near the lodge, but chanced to be seen one day when Mr. Edward Toomer was there. The brothers were concerned together in breaking pointers and setters, some of their own breeding, and others sent to be broke by different gentlemen: of the latter, although they would stand

and back, many were so indifferent that they would neither hunt, nor express any satisfaction when birds were killed and put before them. The slackness of these dogs first suggested the idea that, by the same method, any other animal might be made to stand, and do as well as any of those huntless and inactive pointers. At this instant the sow passed by, and was remarked as being very handsome. R. Toomer threw her a piece or two of oatmeal roll, for which she appeared grateful, and approached very near; from that time they were determined to make a *sporting pig* of her. The first step was to give her a name, and that of Slut (given in consequence of soiling herself in a bog) she acknowledged in the course of the day, and never afterwards forgot. Within a fortnight she would find and point partridges or rabbits, and her training was much forwarded by the abundance of both which were near the lodge; she daily improved, and in a few weeks would retrieve birds that had run as well as the best pointer, nay, her nose was superior to the best pointer they ever possessed, and no two men in England had better. She hunted principally on the moors and heaths. Slut has stood partridges, black-game, pheasants, snipes, and rabbits, in the same day, but was never known to point a hare. She was seldom taken by choice more than a mile or two from the lodge, but has frequently joined them when out with their pointers, and continued with them several hours. She has sometimes stood a jack-snipe when all the pointers had passed by it: she would back the dogs when they pointed, but the dogs refused to back her until spoke to, their dogs being all trained to make a general halt when the word was given, whether any dog pointed or not, so that she has been frequently standing in the midst of a field of pointers. In consequence of the dogs not liking to hunt when she was with them (for they dropped their sterns and showed symptoms of jealousy,) she did not very often accompany them, except for the novelty, or when she accidentally joined them in the forest. Her pace was mostly a trot, was seldom known to gallop, except when called to go out shooting; she would then come home off the forest at full stretch, for she was never shut up but to prevent her being out of the sound of the call or whistle when a party of gentlemen had appointed to see her out the next day, and which call she obeyed as regularly as a dog, and was as much elevated as a dog upon being shown the gun. She always expressed great pleasure when game, either dead or alive, was placed before her. She has frequently stood a single partridge at forty yards' distance, her nose in an exact line, and would continue in that position until the game moved: if it took wing, she would come up to the place, and put her nose down two or three times; but if a bird ran off, she would get up and go to the place, and draw slowly after it, and when the bird stopped she would stand it as before. The two Mr. Toomers lived about seven miles apart, at Rhinefield and Broomey lodges; Slut has many times gone by herself from one lodge to the other, as if to court the being taken out shooting. She was about five years old when her master died, and, at the auction of his pointers, &c., was bought in at ten guineas. Sir Henry Mildmay having expressed a wish to have her, she was sent to Dogmersfield Park, where she remained some years. She was last in the possession of Colonel Sykes, and was then ten years old, and had become fat and slothful, but could point game as well as ever. She was not often used, excepting to

show her to strangers, as the pointers refused to act when out with her. When killed she weighed 700 lbs. Her death-warrant was signed in consequence of her having been accused of being instrumental to the disappearance of sundry missing lambs.”*

Colonel Thornton also had a sow which was regularly taught to hunt, quarter the ground, and back the other pointers.

Some thirty years since it was mentioned in the public papers that a gentleman had trained swine to run in his carriage, and drove four-in-hand through London with these curious steeds. And not long since the market-place of St. Albans was completely crowded in consequence of an eccentric old farmer, who resided a few miles off, having entered it in a small chaise-cart drawn by four hogs at a brisk trot, which pace they kept up a few times round the area of the market-place. They were then driven to the wool-pack yard, and after being unharnessed were regaled with a trough of beans and wash.

A gentleman present offered 50*l.* for the whole concern as it stood, but his offer was indignantly declined. In about two hours the animals were re-harnessed, and the old farmer drove off with his extraordinary team. He stated that he had been six months in training them.

Nor are these cases without parallel, for Montfaucon informs us that Heliogabalus, the Roman emperor, trained boars, stags, and asses to run in his chariot; and Pennant states that in Minorca, and that part of Murray which lies between the Spey and Elgin, swine have been converted into beasts of draught, and that it is by no means unusual to see a cow, a sow, and two young horses yoked together in a plough, and that the sow is the best drawer of the four. In Minorca, the ass and hog may be regularly seen working together in turning up land.

Henderson gives another, and a very simple account, illustrative of the tractability of swine:—

“About twenty-five years ago my father farmed very extensively in various parts of the kingdom, and upon one of his farms in Redkirk, in the parish of Gretna Green, Dumfriesshire, kept at times upwards of one hundred swine. It so happened that the keeper of that flock was either taken unwell or abruptly left his service one harvest, when every creature able to work was employed in reaping. A brother and I being the only idlers about the premises, the above flock was given in charge to us for a few days, until a proper keeper was found; we were then reluctantly obliged to march off with our ‘birsels’ early every morning to a clover-field about a mile distant, with our dinners, books, and great-coats, &c. packed upon our backs: we, however, soon began to think it was a great hardship for us to be groaning under our loads while so many stout able ponies were trotting along before us at their ease, and immediately set about training one of them to relieve us of our burdens, which we accomplished in a few days by occasionally scratching the animal and feeding it with bread, &c. out of our hands. It became at last so docile as to stand every morning until it received the burden girthed upon it, and then marched on in the rear, which place it was trained to keep, as we had more than once lost our dinners when it was allowed to join the herd; and in the same manner we soon trained two or three more into carrying the baggage in turns.

Having been so successful in this training exploit, we then thought it would be turning our punishment into pleasure if we could train each of us one to ride: this was no sooner thought of than commenced, and although we received many a tumble, yet we soon accomplished our design, and succeeded in breaking in each two or three chargers. At length our system became so complete, that we not only rode to and from the field, but whenever any of the herd were likely to stray, or go into some adjoining field of corn, &c., each alternately mounted his charger, and went off at full gallop to turn back and punish the transgressors.

"Such as were trained seldom or never went astray, being always about hand, and in readiness to be mounted; in short, on such days as my father was from home, it was not unusual for a group of servants to receive amusement from my brother and I running set matches with our steeds, which were determined in the usual manner, with whip and spur; and in this latter management there was no such thing as bolting or tumbling going on, which occurred frequently during the training season. This system however, came at length to my father's ears, from one or two of the racers happening to die in consequence of too severe heats, or too much weight; when we were immediately disbanded from our office, and (our holidays being expired) ordered off to school again, which we set about with as much reluctance as we did the first morning in driving the hundred swine to the clover field."*

The learned pig is another illustration of this same quality. This creature had been taught to pick up letters, written upon pieces of card, at command, and arrange them into words. It was first exhibited in the vicinity of Pall-Mall, in 1789, at 5s. each person. The price of admission was afterwards reduced to 2s. 6d., and finally to 1s.

The showman stated that he had lost three pigs in the course of training. Since then there have been many successors of the "learned pig" exhibited at different places, but none equal in talent to the original.

The next thing which we shall claim for our porcine clients is sagacity; nor are we here in want of illustrative evidences of their possession of it. But in general there is nothing in the life of a pig, in his domesticated state at least, which calls for any exercise of reasoning powers. His sole business is to eat, drink, sleep, and get fat; all his wants are anticipated, and his world is limited to the precincts of his sty or of the farm-yard. Yet even in this state of luxurious ease individuals have shown extraordinary intelligence.

Mr. Craven relates the following anecdote of an American sow:—
"This animal passed her days in the woods, with a numerous litter of pigs, but returned regularly to the house in the evening, to share with her family a substantial supper. One of her pigs was, however, quietly slipt away to be roasted; in a day or two afterwards another; and then a third. It would appear that this careful mother knew the number of her offspring, and missed those that were taken from her, for after this she came alone to her evening meal. This occurring repeatedly, she was watched out of the wood, and observed to drive back her pigs from its extremity, grunting, with much earnestness, in a manner so

* Henderson's Practical Grazier.

intelligible, that they retired at her command, and waited patiently for her return."

Surely this must be the result of something very like reasoning powers? "A gentleman residing at Caversham bought two pigs at Reading market, which were conveyed to his house in a sack, and turned into his yard, which lies on the banks of the river Thames.

"The next morning the pigs were missing. A hue and cry was immediately raised, and towards the afternoon a person gave information that two pigs had been seen swimming across the river at nearly its broadest part.

"They were afterwards observed trotting along the Pangbourn road, and in one place where the road branches off, putting their noses together as if in deep consultation. The result was their safe return to the place from which they had originally been conveyed to Reading, a distance of nine miles, and by cross roads.

"The farmer from whom they had been purchased, brought them back to their owner, but they took the very first opportunity again to escape, recrossing the water like two dogs, thus removing the stigma on their race, which proverbially disqualifies them for "swimming without cutting their own throats," and never stopped until they found themselves at their first home."

Here we see difficulties overcome, and a strange element encountered, in order to arrive at a far distant spot—the home to which the animals were attached. Some recollection of that place or some association of ideas must have influenced the proceedings of these animals; but to what faculty shall we attribute their swimming the river in a direct line with their old master's house, and then finding their way so immediately thither? And how shall we account for their thus acting in concert, if pigs are to be considered as the stupid obtuse brutes most persons are in the habit of designating them? Such instances of sagacity in the dog and the horse scarcely astonish us, because we allow to them a certain degree of reasoning power. But is not the great development of it in them as much arising from their intercourse, if such we may term it, with man?—from their being his companions, educated and ordered by him? "I have observed great sagacity in swine," observes Darwin, in his "Zoonomia," "but the short lives we allow them, and their general confinement, prevent their improvement, which would otherwise probably equal that of the dog."

"The Naturalist's Library" gives another anecdote of a pig which is indicative of no small degree of instinct or intelligence:—

"Early in the month, a pig that had been kept several days a close prisoner to his sty, was let out for the purpose of its being cleaned and his bed replenished. On opening the sty-door he anticipated the purpose of his liberation by running to the stable, from which he carried several sheaves of straw to his sty, holding them in his mouth by the hand. The straw being intended for another purpose, it was carried back to the stable; but our porter, seizing a more favourable opportunity, regained it to the amazement of several persons, who were pleased to observe the extraordinary instinct of this wonderful pig."

Swine have also been repeatedly known to attach themselves to individuals, and to other animals, and to manifest great docility, gentleness, and affection.

Mr. Henderson says, "I have a young sow of a good breed, so docile that she will suffer my youngest son, three years of age, to climb upon her back and ride her about for half an hour at a time, and more; when she is tired of the fun, she lays herself down, carefully avoiding hurting her young jockey. He often shares his bread and meat with her."*

A pig belonging to a baker in Kinghorn, county Fife, became so attached to a bull-dog that it would follow and sport with him, and follow her master, when he was accompanied by this dog, for five or six miles. The dog was fond of swimming, and the pig imitated this propensity; and if any thing was thrown into the water for the dog to fetch out, the pig would follow and dispute the prize with him very cleverly and energetically. These two animals invariably slept together.

M. de Dieskau tells us that "he made a wild boar so tame that the animal, although nearly three years old, would go up stairs to his apartment, fawn upon him like a dog, and eat from his hand. He also endeavoured to bring up one which he caught very young, and which formed such an attachment to a young lady in the house that he accompanied her wherever she went, and slept upon her bed. Once he attacked her maid as she was undressing her mistress, and, had he been strong enough, would have done her some mortal injury. This lady was the only person in the house for whom the creature showed any affection, and yet he was not fed by her. At last he fretted himself to death on account of a fox which had been taken into the house to be tamed."

A very amusing account of a "pet pig" is given by a lady, in "Chamber's Edinburgh Journal:"—

"Being at a loss what to do with the refuse of our garden, Aunt Mary suggested that a pig should be purchased. Accordingly our little damsel Annette was despatched to a neighbouring farmer, and in exchange for a few shillings she brought home a fat, fair, round pig, just six weeks old; and in her haste to display her bargain she tumbled it out in the sitting-room. Nothing daunted by the splendour of its new abode, the pig ran up and down, snorting and snuffing at every chair and table in the room, overturning with his snout my aunt's footstool, and trying its teeth on her new straw work-basket. After the pig had been duly admired and commented on, Annette was desired to instal it in its own domicile; but this was more easily said than done; for being, I suppose, pleased with his quarters, Toby—for so we named him—ran hither and thither, now scudding behind a chair or table, now whisking under the sofa; at length Annette succeeded in dragging him from his hiding-place, while he roared out 'Murder!' as plain as a pig could speak. Annette was very fond of dumb creatures, as she called them; the pig became her darling, and for want of a companion of her own species, Toby became her constant associate; and finding his visits to the kitchen were winked at, he made use of the privilege, and would bask himself at full length before the fire. He even ventured occasionally to follow her into the front lobby; and if, as sometimes was the case, she put him into the yard, he would kick up such a row

* Henderson on Swine.

at the kitchen door, to be let in, thumping on it with his snout, that she was fain to admit him to his old quarters. Toby was of a very social disposition, and so fond of Annette, and so grateful for her kindness, that he would follow her about every where; indeed, to my great surprise, one day I found him standing sentry over her while she was putting down the stair carpet, and he seemed to be watching her proceedings with a very sagacious air. In process of time there came another proof that the course of true love never did run smooth. Annette fell into bad health, and returned to her home; the damsel who replaced her had no taste for the society of pigs; so she thumped Toby away from the kitchen door, and many were the blows he got from her broom, or whatever missile came first to hand. Toby was now exiled to his sty, much against his inclination, for he evidently would have preferred bivouacking in the back premises. We seldom passed to the garden without throwing him some comfort in the shape of a few cabbage-leaves, a handful of acorns, or a bunch of turnip-tops. It was truly amusing to see Toby make his bed. As the straw which was furnished for it was rather long and coarse, Toby used to take it bunch by bunch in his teeth, and run into a corner, breaking it into small pieces; and having accomplished this feat, he proceeded to arrange his couch in the most methodical manner. One day, Betty having omitted to give him his dinner, Toby, in a great passion, jumped out of his sty, and came running to the kitchen door to see what was the reason of his being so shamefully neglected, and loud and long were his remonstrances on the subject. Finding it difficult to get the poor animal properly attended to, he was transferred to a neighbour; and we never gave him a successor, as we scarcely expected to find in another of his species that gratitude for kindness, and affection for his friends, which shone so conspicuous in the character of poor Toby.”*

It may appear absurd to claim cleanliness as a swinish virtue; but in point of actual fact the pig is a much more cleanly animal than most of his calumniators give him credit for being. He is fond of a good cleanly bed; and often, when this is not provided for him, it is curious to see the degree of sagacity with which he will forage for himself. “A hog is the cleanliest of all creatures, and will never dung or stale in his sty if he can get forth,” says a quaint old writer of the sixteenth century, and we are very much of his opinion. But it is so much the habit to believe that this animal may be kept in any state of filth and neglect, that “pig” and “pig-sty” are terms usually regarded as synonymous with all that is dirty and disgusting.

His rolling in the mud is alleged against him as a proof of his filthy habits; if so, the same accusation applies to the elephant, the rhinoceros, and other of the Pachydermata. May this not rather be for the purpose of cooling themselves, and keeping off flies, as we admit it to be in the case of the animals above mentioned? Savages cover themselves with grease in hot climates in order to protect their skins; may not instinct teach animals to roll themselves in mud for a similar purpose?†

* Chambers's Edinburgh Journal, vol. v.

† “The Hog, tho' he lumbe in the dirte in the summer, is not a filthie animal. He doeth it, partlie to cool himselfe, partlie to kill his lice; for when the dirte is drie he rubbeth it off, and thereby destroyeth the lice.”—*Hartlieb's Last Legacies*.

Pigs are exceedingly fond of comfort and warmth, and will nestle together in order to obtain the latter, and often struggle vehemently to secure the warmest berth.

They are eminently sensitive of approaching changes in the weather, and may often be observed suddenly to leave the places in which they had formerly been quietly feeding, and run off to their sties at full speed, making loud outcries. When storms are overhanging, they collect straw in their mouths, and run about as if inviting their companions to do the same; and if there is a shed or shelter near at hand, may be seen to carry and deposit it there, as if for the purpose of preparing a bed. Hence has arisen the common Wiltshire saying, "Pigs see the wind." Virgil, in enumerating the signs of settled fine weather, notices this peculiarity in swine:—

"Nor sows unclean are mindful to provide
Their nestling beds of *mouth-collected* straw!"

Foster says—"When hogs shake the stalks of corn, and thereby spoil them, it indicates rain; and when they run squeaking about and throw up their heads with a peculiar jerk, windy weather is about to commence."

Darwin observes—"It is a sure sign of a cold wind when pigs collect straw in their mouths, and run about crying loudly. They would carry it to their beds for warmth, and by their calls invite their companions to do the same, and add to the warmth by numerous bedfellows."*

In their domesticated state swine certainly are very greedy animals; eating is the business of their lives; nor do they appear to be very delicate as to the kind or quality of the food which is set before them. Although naturally herbivorous animals, they have been known to devour carrion with all the voracity of beasts of prey, to tear and mangle infants, and even gorge their appetites with the living limbs of their own young.

Low, however, says—"Instances have occurred in which a sow has been known to devour her young; but rarely, if ever, does this happen in a state of nature. It is not unreasonable to believe that when an act so revolting does occur, it arises more from the pain and irritation produced by the state of confinement, and often filth, in which she is kept, and the disturbances to which she is subjected, than from any actual ferocity: for it is well known that a sow is always unusually irritable at this period, snapping at all animals that approach her. If she is gently treated, properly supplied with sustenance, and sequestered from all annoyance, there is little danger of this ever happening."†

Roots and fruits are the natural food of the hog, in a wild as well as a domesticated state; and it is evident that, however omnivorous this animal may occasionally appear, its palate is by no means insensible to the difference of eatables, for whenever it finds variety it will be found to select the best with as much cleverness as other quadrupeds. "In the peach-tree orchards of North America," says Pennant, "where hogs have plenty of delicious food, they have been observed to neglect the fruit that has lain a few hours upon the ground, and patiently wait for a considerable time for a fresh windfall."

* Darwin's Zoonomia.

† Domesticated Animals of the British Islands.

According to Linnæus the hog is more nice in the selection of his vegetable diet than any of our other domesticated herbivorous animals. This great naturalist states that—

The Cow	eats 276 plants and rejects 218
„ Goat	„ 449 „ 126
„ Sheep	„ 387 „ 141
„ Horse	„ 262 „ 212
but that the Hog only	„ 72 „ 171

They are gifted with an exquisite sense of smell as well as touch, residing in the snout, and this enables them to discover roots, acorns, earth-nuts, or other delicacies suitable to their palates, which may be buried in the ground.

In some parts of Italy swine are employed in hunting for truffles that grow some inches below the surface of the soil, and form those pickles and sauces so highly esteemed by epicures. A pig is driven into a field and there suffered to pursue his own course. Wherever he stops and begins to root with his nose, truffles will invariably be found.

The last charge which we shall endeavour to refute is that of intractability. All the offences which swine commit are attributed to an innately bad disposition; whereas they too often arise solely from bad management or total neglect. Would horses or cattle behave one iota better, were they treated as pigs too often are? They are legitimate objects for the sport of idle boys, hunted with dogs, pelted with stones, often neglected and obliged to find a meal for themselves, or wander about half-starved. Can we wonder that, under such circumstances, they should be wild unmanageable brutes? Look at the swine in a well regulated farm-yard—they are as peaceable and as little disposed to wander or trespass as any of the other animals that it contains. Here, as in many other things, man is but too willing to attribute the faults which are essentially of his own causing, to any other than their true source.

CHAPTER IV.

The Wild Boar—Description of him—Characteristics—The female and her young—Hunting the Wild Boar—Homer's description of a Boar-hunt—Roman festivals and games—the Wild Boar in England and Scotland—In France—In Germany—Mode of hunting the Boar in Germany—Wild Boar park of the Emperor of Austria—Present wild breed in Germany—In Hungary—In the Styrian Alps—In Russia and Sweden—In the East—Habits of the Wild Hog in India—Wild Hog hunting in India—The wild breed in America—Fearful conflict with a wild herd in Columbia—The Wild Boar the parent stock of all domesticated breeds—Resemblances between—Alterations produced by Domestication—Reassumption of old habits on again becoming free from control of man.

THE wild boar (*sus scrofa*; var. *aper*) is generally admitted to be the parent of the stock from which all our domesticated breeds and varieties have sprung. This animal is generally of a dusky brown or iron-gray colour, inclining to black, and diversified with black spots or streaks. The body is covered with coarse hairs, intermixed with a downy wool; these hairs become bristles as they approach the neck and shoulders, and are here so long as to form a species of mane, which the animal erects when irritated. The head is short, the forehead broad and flat,

the ears short, rounded at the tips and inclined towards the neck, the jaw armed with sharp crooked tusks which curve slightly upwards, and are capable of inflicting fearful wounds, the eye full, neck thick and muscular, the shoulders high, the loins broad, the tail stiff, and finished off with a tuft of bristles at the tip, the haunch well turned, and the legs strong.*

THE WILD BOAR.

The wild boar is a very active and powerful animal, and becomes fiercer as he grows older. When he exists in a state of nature, he will usually be found in moist, shady, and well wooded situations, not far remote from streams or water. In India they are found in the thick jungles, in plantations of sugar-canes, rice, or rhur, or in the thick patches of high, long grass.† In England, France, Germany, Italy,

* A full grown wild boar in India averages from thirty to forty inches in height at the shoulder. The African wild boar is about twenty-eight or thirty inches high.

† The wild hog delights in cultivated situations, but will not remain where water is not at hand in which he can quench his thirst and wallow at his ease, nor will he resort a second season to a spot that does not afford ample cover, either of heavy grass or underwood jungle, within a certain distance for him to fly to in case of molestation; and especially to serve as a retreat during the hot season, as otherwise he would find no shelter. The sugar-cane is his great delight, both as affording his favourite food and yielding a highly impervious, and unfrequented situation. In these the hogs, and the breeding sows especially, commit great devastation, for the latter not only devour but cut the canes for a litter, and to throw up a species of hut, which they do with much art, leaving a small entrance which they can stop up at pleasure. Sows never quit their young pigs without completely shutting them up. This is, however, only requisite for a few days, after which, the little ones may be seen following their mother at a good round pace, though evidently not more than a week or ten days old.—Williamson's Oriental Field Sports.

and Spain, their resorts have been in the woods and forests. This animal is naturally herbivorous, and appears to feed by choice upon plants, fruits, and roots. He will, however, eat the worms and larvæ which he finds in the ground, also snakes and other such reptiles, and the eggs of birds; and Buffon states that wild boars have been seen to devour the flesh of dead horses, while other authors accuse them of devouring hares, leverets, partridges, and indeed all kinds of small game, and feeding greedily upon carrion; but this has also been asserted to be only the case when they are pressed by hunger. They seldom quit their coverts during the day, but prowl about in search of food during twilight and the night. Their acute sense of smell enables them to detect the presence of roots or fruits deeply imbedded in the soil, and they often do considerable mischief by ploughing up the ground in search of them, particularly as they do not, like the common hog, root up a little spot here and there, but plough long continuous furrows.

The wild boar, properly so called, is neither a solitary nor a gregarious animal. For the first two or three years the whole herd follows the sow, and all unite in defence against any enemies, calling upon each other with loud cries in case of emergency, and forming in regular line of battle, the weakest occupying the rear. But when arrived at maturity the animals wander alone, as if in perfect consciousness of their strength, and appear as if they neither sought nor avoided any living creature. They are said to live about thirty years; as they grow old the hair becomes gray, and the tusks begin to show symptoms of decay. Old boars are rarely found associating with a herd, but seem to keep apart from the rest, and from each other.

The female produces but one litter in the year, and her litters are much smaller in number than those of the domestic pig; she carries her young sixteen or twenty weeks, and generally is only seen with the male during the rutting season. She suckles her young for several months, and continues to protect them for some time afterwards; if attacked then, she will defend herself and them with exceeding courage and fierceness. Many sows will often be found herding together, each followed by her litter of young ones, and in such parties they are exceedingly formidable to man and beast. Neither they or the boar, however, appear to want to attack any thing, but only when roused by aggression, or disturbed in their retreat, do they turn upon their enemies and manifest that mighty strength with which nature has endowed them, otherwise they pursue their way in a kind of solitary savage majesty. Occasionally when two males encounter each other, a fierce and furious battle will ensue, especially if this happens during the rutting season, when their passions are inflamed. When attacked by dogs, the wild boar at first sullenly retreats, turning upon them from time to time, and menacing them with his tusks; but gradually his ire rises, and at length he stands at bay, fights furiously for his life, and tears and rends his persecutors. He has even been observed to single out the most tormenting of them, and rush savagely upon him.

Hunting the wild boar has been a favourite sport, in almost all the countries in which this animal was found, from the earliest ages. In all the ancient Grecian and Roman classical writers, some allusions to this

animal will be found.* Homer, whose vivid portraiture of the actions and habits of princes and warriors nearly thirty centuries ago are known to almost every scholar, again and again refers to this savage denizen of the forests, nor can we deny ourselves the pleasure of extracting the following graphic lines :—

“Soon as the morn, new roll'd in purple light,
Pierc'd with her golden shafts the rear of night,
Ulysses, and his brave maternal race
The young Antolici, assay the chase;
Parnassus, thick perplex'd with horrid ahades,
With deep-mouth'd hounds the hunter troop invades;
What time the sun from ocean's peaceful stream
Darts o'er the lawn his horizontal beam.
The Pack impatient anuff the tainted gale;
The thorny wilds the woodmen fierce assail;
And foremost of the Train, his cornel spear
Ulysses wav'd to rouse the savage war;
Deep in the rough recesses of the wood,
A lofty copse, the growth of ages stood;
Nor winter's boreal blast, nor thund'rous show'r,
Nor solar ray could pierce the shady bower,
With wither'd foliage strew'd, a heapy store!
The warm pavilion of a dreadful boar.
Rous'd by the hounds' and hunters' mingling cries,
The savage from his leafy shelter flies,
With fiery glare his sanguine eye-balls shine
And bristles high impale his horrid chine.
Young Ithacus advanced, defies the foe,
Poising his lifed lance in act to throw:
The savage render'd vain the wound decreed,
And springs impetuous with opponent speed!
His tusks oblique he aim'd, the knee to gore;
Aslope they glanced, the sinewy fibres tore,
And hard the bone: Ulysses undismay'd,
Soon with redoubled force the wound repaid;
To the right shoulder-joint the spear applied,
His further flank with streaming purple dyed;
On earth he rush'd with agonizing pain,
With joy, and vast surprise, the applauding train
Viewed his enormous back extended on the plain.”†

The wild boar formed part of the sports, pageants, and wild-beast shows and fights of the Romans. On the return of Severus from Arabia and Egypt, in the tenth year of his reign, sixty wild boars fought each other; and in the year that Gordian the First was ædile, he entertained the people of Rome, at his own expense, once a month; and “on the sixth month there were two hundred stags, thirty wild horses, one hundred wild sheep, twenty elks, one hundred Cyprian bulls, three

* In hunting the wild boar, javelins and large nets were used. The recent prints of the animal's feet on the ground, the impression of his teeth on the bark of the trees, and other indications, led us to a thick wood (Xenoph. Exped. Cyr. lib. 5.) We loosened a dog of Lacomia, who followed the scent and brought a cry of his discovery. We immediately retired and prepared our nets, and occupied our respective places. The wild boar first comes on our side; far from being entangled in the net, he paused, and for a moment sustained the attack of the whole pack; but their baiting, and the attempts of the hunters to wound him with arrows and stones, caused him to re-enter the forest. He very soon met with Moschion, who awaited him with the intention of spearing him, but the spear glided over the shoulder of the animal and fell from the hands of the hunter, who instantly threw himself down with his face on the ground. I thought that he was lost. Already was the beast about to trample him under foot, when he saw Diodorus, who flew to the aid of his companion. He immediately sprung on this new enemy, who, more skilful or more fortunate, plunged his spear into the joint of the shoulder. We then had a dreadful example of the ferocity of this animal, who, although wounded, continued to advance furiously towards Diodorus, who also kept up the conflict. Several of the dogs were wounded and escaped, but Diodorus was more fortunate.—Vid. Xenoph. de Venat. vol. v. 999, and Voyage du Jeune Anacharsis, vol. iv. 6.

† Homer's *Odyssey*, b. xix. v. 591.

hundred red Barbary ostriches, thirty wild asses, and one hundred and fifty wild boars," given out to be hunted by the populace, and become the property of whosoever was fortunate enough to catch them.*

During the middle ages, hunting the wild boar formed one of the chief amusements of the nobility, in most European countries. The dogs provided for this sport were of the slow heavy kind, anciently known by the name of the "boarhound." None but the largest and oldest boars were hunted, and these afforded a very exciting and often dangerous sport, lasting for many hours; for when first the animals was "reared," he contented himself with slowly going away, just keeping ahead of his pursuers, and apparently caring but little for them, and pausing every half-mile to rest himself, and give battle to his assailants, who are, however, too wary to advance upon him until he becomes tired; then he takes his final stand, and dogs and hunters close around him, and a mortal combat ensues, in which the beast eventually falls a victim.

In treatises on venery and hunting, the technical term for the boar in the first year is "a pig of the sounder;" in the second, "a hog;" in the third, "a hog steer;" and in the fourth, "a boar."

Many of the forests in our own country were infested by wild boars. The Anglo-Saxons seem, from the rude frescoes and prints which are handed down to us, to have hunted this animal on foot with no other weapon but the boar-spear, and attended by powerful dogs; and apparently with such success, that at the Norman conquest William the First thought it necessary to make some strict laws for the preservation of this beast of the chase. The period for hunting the wild boar among the Anglo-Saxons was in September. Howel Dha, the celebrated Welsh lawgiver, gave permission to his chief huntsman to chase the boar from the middle of November until the end of December.†

These animals continued to linger in the forests of England and Scotland for several centuries after the Norman conquest, and many tracts of land have derived their name from this occurrence, while instances of valour in their destruction are recorded in the heraldic devices of many a noble family.‡ Fitzstephen, a writer of the twelfth century, informs us that wild boars, stags, fallow deer, and bulls, abounded in the vast forests which existed on the northern side of London in the time of Henry II. The learned Whittaker informs us that this animal roved at liberty over the woods of the parish of Manchester for many centuries after the Romans departed from that station, and hence the name of Barlow (*boar-ground*) came to be assigned to a district in the south-western portion. In Cumberland, the appellation "Wild Boar's Fell" still points out the haunts of this animal. The forests of Bernwood in Buckinghamshire, of Stainmore in Westmoreland, and those extensive woody districts which once existed in Hertfordshire and over the Chiltern Hills, were formerly peopled with wild boars, wolves, stags, and wild bulls. Many ancient Scottish writers, too, speak of the existence of this animal in the woods of Caledonia. In the county of Fife there exists a tract of country formerly called *Muckross* (which in the Celtic signifies Boar's Promontory); it is said

* Augustan History, vol. ii.

† Leges Wallicæ.

‡ The ancient crest of the family of Edgcumbe was a boar's head crowned with bays upon a charger.

to have been famous as the haunt of wild boars. One part of it was called the Boar Hills, which name has since been corrupted into Byro Hills. It lies in the vicinity of St. Andrew's, and in the cathedral church of that city two enormous boar's tusks were formerly to be seen chained to the high altar, in commemoration of an immense brute slain by the inhabitants after it had long ravaged the surrounding country.*

The precise period at which the wild boar became exterminated in England and Scotland cannot be correctly ascertained. Master John Gifford and William Twety, who lived in the reign of Edward II., composed a book on the craft of hunting, part in verse and part in prose, and among the beasts mentioned in those hunted we find—

"Tn venery I cast me fyrst to go;
Of whiche foure beasts there be; that is to say,
The hare, the herte, the wulfke, the wild boor also."

In the time of Charles I. they had evidently been long extinct, for he endeavoured to re-introduce them, and was at considerable expense in order to procure a wild boar and his mate from Germany. These are said to have been turned into the New Forest, where they propagated greatly. Certain it is, that the breed commonly called "forest pigs," are very different from the true Hampshire, and have many of the characteristics of the wild boar.

Throughout the whole of England the boar's head was formerly a standard Christmas dish, served with many ceremonies, and ushered in by an ancient chorus chanted by all present, the words of which are preserved in "Ritson's Ancient Song:—

"The bore's heed in hand bring I,
With "garlands" gay and rosenary,
I pray you all syng merily,
Qui estis in convivio.

The bore's heed, I understande,
Is the "chefe" serryca in the lande
Loke where ever it be founde,
Servite cum cantico.

Be gladde, lordes, hothe more and lasse,
For this hath ordeyned our stewarde,
Tn chere you all this Christmasse,
The bore's heed with mustarde."

Queen Margaret, wife of James IV. of Scotland, "at the first course of her wedding dinner," was served with "a wyld bore's head gylt within a fayr platter."

King Henry II. himself bore this ancient dish into the hall, attended with trumpeters and great ceremony, when his son was crowned.

The boar's head is to the present day placed upon the table in Queen's College, Oxford, on Christmas-day, but now it is neatly carved in wood instead of being the actual head of the animal. This ceremony is said to have originated in a tabendar belonging to that college having slain a wild boar on Christmas-day, which had long infested the neighbourhood of Oxford. He is said to have been going to serve at church when he met the animal, and to have slain him by thrusting a copy of Aristotle down his throat.

The abbot of St. Germain, in Yorkshire, was bound to send yearly a present of a boar's head to the hangman, which a monk was obliged to

* See Martin's Reliquiæ Divi, and Sibbald's Hist. of Fife.

carry on his own. This rent was paid yearly, at the feast of St. Vincent, the patron of the Benedictines, and on that day the executioner took precedence in the procession of monks.

France, too, formerly had its trackless forests, through which the grisly boar roved in savage grandeur—its boar-hunts—its legends of sanguinary combats with these monsters. The “wild boar of Ardenes” has been the theme of many a lay and romance. But civilization, the increase of population, and the progress of agriculture, have here, too, been at work. Still, however, in the large tracts of forest land which yet exist and supply the towns with fuel, boars are still occasionally to be met with, although they cannot be regarded as so wild or ferocious as the ancient breed. At Chantilly, within forty miles of Paris, the late Prince of Condé, who died in 1830, kept a pack of hounds expressly for the purpose of hunting the boar; and some English gentlemen who visited the hunting palace in the summer of 1830, were informed by the huntsman that a few days previously he had seen no less than fourteen wild hogs at one time. But the good old “wild-boar hunt,” as once existed, with all its perils and excitements, is now extinct in France as well as in Germany. Where any traces of it remain, they resolve themselves into a battue of a most harmless description, which takes place in the parks of the princes or nobles. The drivers beat up the woods, the wild swine run until they come in contact with a fence stretched across the park for the purpose, and about the centre of which, at an opening in the wood, a sort of stage is raised, on which the sportsmen stand and fire at the swine as they run past.

Germany being a country boasting forests of immense extent, was once the most celebrated of all nations for its wild boars and boar-hunts; and in many parts wild hogs are still abundant, and various methods are adopted to destroy them, as well for amusement as to turn their carcases to account, which furnish those finely flavoured hams called Westphalian, and generally supposed to be bears’ hams.

The most simple and effectual way is to find out the haunts of the boar, and place a matchlock on rests well charged, and concealed by brambles near it. A rope is attached to the trigger, and carried below the rests to the trunk of a tree at some little distance, so as to intersect the animal’s path to the forest. Over this the hog inevitably stumbles, and thus discharges the piece, and receives the ball in the neck or shoulder.

The ordinary method of shooting the hog in Germany is as follows:—

The huntsman, or *jäger*, goes out with an ugly but useful animal not unlike a shepherd’s dog, but smaller, which is in German language called a “sow-finder.” The business of this creature is to seek the hog, and so well trained is he that no other animal will turn him from that particular scent. On meeting with the object of his search he gives tongue incessantly, and with active but cautious irritation pursues the boar till he is at bay; then, by continual teasing, he manages to turn him sideways to his master, the shoulder affording the best aim for readily disabling him. In this situation the sagacious dog contrives to keep him until his master fires; then if the wounded boar makes off, the boar-hound (a species of blood-hound) is let loose, who pursues him for miles, giving tongue, nor will he leave him even if other boars come in the way.*

* Foreign Field Sports.

At the wild-boar park of the Emperor of Austria, which is at Hüttelsdorf, near Vienna, Mr. Howitt states that he saw "Numbers of swine of all ages and sizes, from the grisly old boar to the sow and her troop of suckling young ones. Here some grim old fellow as black as jet, or of a sun-burnt and savage gray, lay basking in the deep grass, and at our approach uttered a deep guff, and starting up, bolted into the wood. Others were lying their length under the broad trees, others scampering about with cocked tails. The sows and their young seemed most savage and impatient of our presence. Some were tame enough to come at the whistle of the keeper, and scores ran voraciously when he shook one of the wild cornel-trees, which grew plentifully in the forest. This is a tree as large as an apple-tree, bearing in autumn fruit of about the size of cherries, and of a coral red colour. The swine are very fond of it, and as the trees were shook and it pattered to the ground, they came running on all sides, and stood in the thickets eager for our departure, when they rushed ravenously forward and devoured it."

"After all," he continues, "the wild swine here can present but a faint idea of what they were in their ancient wilds. They are all of the true breed, and cannot for a moment be confounded with the tame variety: there is the tusked mouth, the thick fore-quarter, the narrow hind-quarter, the mane, the coarse bristles, the speed of gait, indicative of the wild breed, but they appeared tame and pigmy in comparison with the huge savage monsters bred in the obscure recesses of deep forests and unacquainted with the sight of man.

"Hunters tell us that, notwithstanding the orders of Government to exterminate swine in the open forests, on account of the mischief they do to cultivated land, there are numbers in the forests in Hanover and Westphalia, huge, gaunt, and ferocious as ever. These will snuff the most distant approach of danger, and with terrific noises rush into the densest woods; or surrounding a solitary and unarmed individual, especially a woman or a child, will scour round and round them, coming nearer and nearer at every circle, until at last bursting in upon them they tear them limb from limb and devour them. Tame swine, which are herded in these forests and become mixed in breed with the wild, acquire the same blood-thirsty propensities, and will in their herds surround and devour persons in a similar manner."*

The wild breed abound in Upper Austria, on the Styrian Alps; and in many parts of Hungary. In the latter country, a recent author speaking of them, says: "These animals have lost some little of their natural ferocity, but they still fly at the approach of strangers, and in their form and habits preserve all the characteristics of the true wild boar, from which stock they are descended without intermixture of any other breed. I am told too that their flesh has all the peculiar flavour of the wild boar. This animal, in a completely savage state, is now becoming very scarce in Hungary, and is only met with in the most secluded forests and in the recesses of the Carpathian mountains.†

The forests of Poland, Spain, Russia, and Sweden‡ still contain ani-

* Howitt's Rural Life in Germany.

† Bright's Travels through Germany and Lower Hungary.

‡ Lloyd, in his "Field Sports of Northern Europe," gives the following account of an encounter with a wild sow:—"One day in the depth of winter, accompanied by my Irish servant, I struck into the forest, in the vicinity of that place for the purpose of shooting capercali. On this occasion, however, we had no other guide than my pocket

imals of the wild boar tribe, and the inhabitants of these countries hunt them with hounds, or attack them with fire-arms or with the proper boar-spear.

But the most exciting accounts we now have of this sport are furnished by our countrymen in the East, who diversify their other hunts and field-sports by occasionally chasing the wild hog. Captain Williamson, in his graphic volume, gives some very animated accounts of the perils of this chase, as does also Mr. Johnston; and if any thing could reconcile us to the pursuing, tormenting, and shedding the blood of an animal who only puts forth his strength in self-defence, it would be the bravery and presence of mind exhibited by some of the huntsmen. One or two quotations will illustrate the habits of the wild hogs of India, as well as the mode in which they are hunted.

"The pace and powers of "the wild hog" are not to be estimated by any comparison with those of the tame one. Persons unacquainted with the vigour and speed of the Jungle hog will be surprised to learn that it requires a good horse to keep near a moderately sized hog, and that it is by no means uncommon to see what is considered as a moderately sized animal overthrow many horses in succession. The fact is, that from April to November, during which period the canes and corn are off the grounds, the wild hogs are compelled to wander from the copses and long grass-jungles in which they take refuge, to greater distances, in search of food, by which means they are not only kept low in flesh, but, from their daily exercise, get confirmed in good wind, and seem rather to attack the hunter than to run away; and this is not merely during the space of a few hundred yards, but for a considerable distance. I recollect being one of four well-mounted riders, who were completely distanced in a chase of about three miles.

"In crossing the country early in June, about sunrise, we saw at a considerable distance a hog trotting over a plain to his cover, which was a large extent of brambles and copse, from which we could not hope to drive him. As there appeared no chance of overtaking him, we agreed to let him proceed unmolested, and to be at the place whence he had come by daybreak on the next morning. We accordingly were up early on the following morning, anticipating the pleasure of being at his heels, but on arriving at the spot in which we had observed him on the preceding day we found him nearer to his cover than before.

"Knowing that when hogs take the alarm they are apt to change

compass. Towards evening, and when seven or eight miles from home, we came to a small hamlet, situated in the recesses of the forest; here an old wild sow and her progeny made a determined dash at a brace of very valuable pointers I at that time had along with me, who naturally took shelter behind us. My man had a light spear in his hand, similar to those used by our lancers; this I took possession of, and directing him to throw the dogs over a fence, in the angle of which we were cooped up, I placed myself between the dogs and their pursuers. The sow, nevertheless, still pressed forward, and it was only by giving her a severe blow across the snout with the butt end of the spear, that I stopped her further career. Nothing daunted, however, by this reception, she directed her next attack against myself; when, in self-defence, I was obliged to give her a home-thrust with the point of the spear. These attacks she repeated three several times, and as often got the spear up to the hilt either in her head or neck. She then slowly retreated, bleeding at all pores: so savage and ferocious a beast I never saw in my life. In the fray I broke my spear, which was as well, for it was by no means strong enough to answer the purpose for which it was intended.

"This was not a solitary instance of the ferocity of the wild swine. It was the same throughout Sweden; whenever they caught sight of my dogs, they generally charged, and if they came up with them, would tumble them over and over again with their snouts."

their route and their hours, we were not surprised at this manœuvring. We were still earlier on the third morning, when we took our positions nearer his place of nightly resort, and had the satisfaction to find that we were in time to bear him company homeward. Here, however, some delay took place. The hog on his first breaking from the small jungle where we awaited him, and through which he had to pass, after glutting himself in a swamp among some rye, sown extremely thick for transplanting, found that he was watched. He, therefore, after trotting out a hundred yards, gave a sort of snort and returned. This was precisely what we wished for.

"It was not yet day, and the desire to intercept our prey had made us push forward so as to place our people far behind. They, however, came up to the number of a hundred, and after beating the cover for a short time, our friend took fairly to the plain.

"As we were careful not to dispirit, and had cautiously kept from that side on which we wished him to bolt, he gained upon us a little. He had to go at least three miles, and the whole of the plain was laid out in *paddy* or rice fields.

"The hog kept a-head the whole way, so that there was no possibility of our throwing a distant spear.

"The swine generally establish themselves in cane or grain plantations, when these are high and afford good shelter, and here they live for several months; but about the middle of March, or, at the latest, the beginning of April, they are obliged to shift their quarters, as the cane and grains are generally cut about that time. However, they often retain possession to the last moment, disputing every inch with the reapers, and not rarely causing them to leave parts uncut, in the hope that the hogs will evacuate them, which, if the jungles to which they must betake themselves happen to be remote, they feel no great disposition to do, for at this season the hog is indolent and heavy, in consequence of the abundance of the excellent food to which he has for five or six months been habituated.

"Hogs are often found in March with three or four inches of fat on the chins and shoulders.

"It usually requires a great number of persons to drive the hogs out of the sugar-canes, on account of their extent. The beaters should not be more than five or six yards distant from each other, or they will turn back and rush through the intervals. Small drums should be used to frighten them out; sometimes this will be troublesome; it is particularly so with a sow that has 'pigs:' she will frequently come to the edge, and dash through the line of beaters again and again. The hog is generally hunted on horseback, but elephants are likewise employed in this sport, in which tigers are not unfrequently dislodged from their retreats.

"The hog, being forced from his covert, is crowded on by several horsemen with spears, which they use in the manner of javalins. They pursue the animal at speed as he makes his way to the nearest cover, darting their spears into his body as they come up to him. Those horsemen," says Captain Williamson, "who are placed at the nearest situation, should gallop round to watch the hog passing, and giving the loud halloo, should dash at him at full speed, spearing as they come up. Some hogs, however, are aware of the plot, having been hunted before.

"Many may be seen with scars, evidently the result of wounds received on former occasions, and such are extremely difficult to deal with. They will break out of the line repeatedly, dash at all they meet with, and eventually create such terror as effectually to discourage the beaters, who thence get into groups, and, though they continue their vociferation, act so timorously as to render it expedient to withdraw them for the purpose of trying a fresh cover. It is very common to see a plough at work at the very edge of the canes where the villagers are beating for hogs; and as the bullocks employed are extremely skittish and wild, it often happens that they take fright and run off with the plough, which frequently is broken to pieces. The ploughman, alarmed equally with his cattle, also takes to flight, as do all the peasants who may see the bristling animal galloping from his haunt."*

Mr. Johnston describes another scene eminently characteristic of the desperate fierceness and strength of the wild hog. He was one of a party of eight persons, on a sporting excursion near Patna on the banks of the Soane. Returning one morning from shooting, they met with a very large boar, which they did not fire at or molest, as, although several of the party were fond of hunting, they had no spears with them. The next morning they all sallied forth in search of him, and just as they had arrived at the spot where they had seen him the day before, they discovered him at some distance galloping off towards a grass jungle on the banks of the river. They pressed their horses as fast as possible, and were nearly up with him when he disappeared all at once.

The horses were then nearly at their full speed, and four of them could not be pulled up in time to prevent their going into a deep branch of the river, the banks of which were at least fourteen or fifteen feet high. Happily, there was no water in, or any thing but fine sand, and no person was hurt. One of the horses, that was exceedingly vicious, got loose, attacked the others, and obliged them, and all the rest, to recede.

A few days afterwards they went again, early in the morning, in pursuit of the same hog, and found him farther off from the grass jungle, in a rbur-field, from which with much difficulty they drove him into a plain, where he stood at bay challenging the whole party, and boldly charging every horse that came within fifty yards of him, grunting loudly as he advanced.

"The horse I rode," says Mr. Johnston, "would not go near him; and when I was at a considerable distance off, he charged another horse with such ferocity that mine reared and plunged in so violent a manner as to throw me off. Two or three others were dismounted at nearly the same time; and though there were many horses present that had been long accustomed to the sport, not one of them would stand his charges. He fairly drove the whole party off the field, and gently trotted on to the grass jungle, foaming and grinding his tusks."†

In Morocco the wild boar is the most common and prolific of all the ferocious animals found there; the sow produces several large litters in the year; and were it not that the young form the favourite food of the lion, the country would be overrun with these animals.

* Williamson's Oriental Field Sports.

† Johnston's Indian Field Sports.

In the woods of America there are abundance of wild swine, possessing all the ferocity of the boar. The following fearful scene occurred in Columbia. A party of six hunters had gone out on a sporting expedition. They fell in with a herd of swine, upon which four of them, less experienced than the others, immediately fired, and the swine advanced fiercely to attack them. The four young men, intimidated, took to flight without warning their companions, or considering the danger to which they were exposed. They climbed up into some trees, but the other two were quickly surrounded by the swine. They made a long and desperate defence with their lances, but were at length dragged down. One of them was torn to pieces, and the other dreadfully lacerated and left for dead by the swine, who now watched the four fugitives in the trees until sunset. Then, probably yielding to the calls of nature, they retired. The surviving hunters then came down and assisted their wounded companion into the canoe, and carried off the remains of the unfortunate man who had fallen in this horrible encounter.*

We have entered thus much at length into the history of the wild boar, because no one can for a moment doubt that it is the parent stock from which the domesticated breeds of swine originally sprung; the well known fact that all kinds breed with the boar, is in itself a sufficient testimony; but to this we can add that the period of gestation is the same in the wild and tame sow; the anatomical structure is identical; the general form bears the same characters; and the habits, so far as they are not altered by domestication, remain the same.

Where individuals of the pure wild race have been caught young and subjected to the same treatment as the domestic pig, their fierceness has disappeared, they have become more social and less nocturnal in their habits, lost their activity, and lived more to eat. In the course of one or two generations even the form undergoes certain modifications; the body becomes larger and heavier; the legs shorter and less adapted for exercise; the formidable tusks of the boar, being no longer needed as weapons of defence, disappear; the shape of the head and neck alters; and in character as well as in form, the animal adapts itself to its new position. Nor does it appear that a return to their native wilds restores to them their original appearance, for, in whatever country pigs have escaped from the control of man and bred in the woods and wildernesses, there does not appear to be a single instance recorded by any naturalist in which they have resumed the habits and form of the wild boar. They become fierce, wild, gaunt, and grisly, and live upon roots and fruits; but they are still merely degenerated swine, and they still associate together in herds, nor "walk the glade in savage solitary grandeur" like their grim ancestors.

We shall now proceed to notice some of the accounts given of the swine found in various parts of the world, previous to entering upon a consideration of the breeds peculiar to our own country.

* Cochrane's Columbia, vol. i.

CHAPTER V.

Swine in AMERICA—In large towns—Original breed—Improved breed—Swine in Canada—In Ohio—In Mexico—Hebrides—In Columbia—In the South-Sea Islands—Swine in ASIA—In China and Japan—Ceylon—Hindustan—Turkey and Arabia—Swine in AFRICA—Guinea—New Holland—Caffraria—Swine in EUROPE—In Malta—In Italy—In Germany—In Hungary—In Russia—In Sweden—In France—Swine indigenous to the CHANNEL ISLANDS—In Jersey—In Guernsey—In Serk—In Alderney—The Isle of Man—In the Hebrides—In the Shetland Isles—In the Orkneys.

AMERICA.

THROUGHOUT the whole of this quarter of the globe swine appear to abound. They are not, however, indigenous, but were doubtless originally carried thither by the early English settlers, and the breed thus introduced still may be distinguished by the traces they retain of their parent stock; but France, Spain, and, during the slave-trade, Africa, have also combined to supply America with varieties of this animal, so useful to the settler in the wilds and woods, and so much esteemed throughout the whole of the country, as furnishing a valuable article of food.

"It appears that the American zoologists describe no fewer than six species of the hog, some of them so entirely distinct in their general habits and appearance as to prevent their ever breeding or even associating together. Five of these species need only be regarded as objects of curiosity; the sixth is the common wild hog of the eastern continent—which we will describe in order to illustrate the difference between a good and a bad animal of the same variety; they have long-peaked snouts, coarse heads, thin chests, narrow shoulders, sharp backs, slab sides, meagre diminutive hams, big legs, clumped feet, the hide of a rhinoceros, the hair and bristles of a porcupine, and as thick and shaggy as a bear's; they have no capacity for digesting and concocting their food in the stomach for nourishment; there is nothing but offal, bones, rind, bristles and hair, with a narrow streak of gristle underneath, and a still narrower line of lean, as tough and as rank as white leather—their snouts against every man, and every man's hand against them. No reasonable fence can stop them, but, ever restive and uneasy, they rove about seeking for plunder; swilling, grunting, rooting, pawing, always in mischief and always destroying. The more a man possesses of such stock the worse he is off; and he had far better sell his produce at any price, than to put it into such totally worthless creatures."*

Stuart says—"Hogs are universal in this part of the world, and are well and frequently fed. At first they are kept in the woods, and nurtured on chestnuts and apples; before being killed, they have good rations of Indian corn or barley-meal, and in many cases are likewise well supplied with steamed food. In South Carolina the climate is so mild that they are allowed to wander about the woods during the whole year, feeding on the nuts, acorns, &c. which are there so abundant, and occasionally eating the fallen fruit they meet with. They are very useful in destroying snakes."†

In large towns, too, they are apparently as much at home and as com-

* A. B. Allen.

† Stuart's North America.

mon as in the forests, pacing the streets, instead of the glades, and feeding upon the offal and filth rejected by man, instead of the fresh and wholesome fruits supplied by the hand of nature. One of our countrymen gives an amusing graphic account of the swinish multitude in some of the large towns through which he passed.

"We are going to cross here. Take care of the pigs. Two portly sows are trotting up behind this carriage, and a select party of half-a-dozen gentlemen hogs have just now turned the corner. Here is a solitary swine, lounging homewards by himself; he has only one ear, having parted with the other to vagrant dogs in the course of his city rambles; but he gets on very well without it, and leads a roving, gentlemanly, vagabond kind of life, somewhat answering to that of our clubmen at home. He leaves his lodgings every morning at a certain hour, throws himself upon the town, gets through his day in some manner quite satisfactory to himself, and regularly appears at the door of his own house again at night, like the mysterious master of Gil Blas; he is a free-and-easy, careless, indifferent kind of pig, having a very large acquaintance among other pigs of the same character, whom he rather knows by sight than conversation, as he seldom troubles himself to stop and exchange civilities, but goes grunting down the kennel, turning up the news and small-talk of the city, in the shape of cabbage-stalks and offal, and bearing no tails but his own, which is a very short one, for his old enemies the dogs have been at that too, and have left him hardly enough to swear by; he is in every respect a republican pig, going wherever he pleases and mingling with the best society, on an equal if not superior footing, for every one makes way when he appears, and the haughtiest give him the wall if he prefer it; he is a great philosopher, and seldom moved unless by the dogs before mentioned; sometimes, indeed, you may see his small eye twinkling on a slaughtered friend, whose carcass garnishes a butcher's door-post, but he grunts out "Such is life; all flesh is pork!" buries his nose in the mire again, and waddles down the gutter, comforting himself with the reflection that there is one snout the less to anticipate stray cabbage-stalks, at any rate.

"They are the city scavengers; these pigs, ugly brutes they are; having for the most-part scanty brown backs, like the lids of old horse-hair trunks, spotted with unwholesome black blotches; they have long gaunt legs too, and such peaked snouts that if one of them could be persuaded to sit for his profile, nobody would recognize it for a pig's likeness; they are never attended upon, or fed, or driven, or caught, but are thrown upon their own resources in early life, and become preternaturally knowing in consequence; every pig knows where he lives much better than any body could tell him. At this hour, just as evening is closing in, you will see them roaming towards bed by scores, eating their way to the last. Occasionally some youth among them who has over eaten himself, or has been worried by dogs, trots shrinkingly homeward, like a prodigal son; but this is a rare case; perfect self-possession and self-reliance, and immovable composure, being their foremost attributes."*

And Mrs. Trollope piteously exclaims—"I am sure I should have

* Dicken's American Notes.

liked Cincinnati much better if the people had not dealt so very largely in hogs! The immense quantity of business done in this line would hardly be believed by those who had not witnessed it. I never saw a newspaper without remarking such advertisements as the following: "Wanted immediately, 4000 fat hogs;" "For sale, 2000 barrels of prime pork." But the annoyance came nearer than this. If I determined upon a walk up Main Street, the chances were five hundred to one against my reaching the shady side without brushing by a snout or two, fresh dripping from the kennel. When we had screwed up our courage to the enterprise of mounting a certain noble-looking sugar-loaf hill, that promised pure air and a fine view, we found the brook we had to cross at its foot red with the blood from a pig slaughter-house; while our noses, instead of meeting "the thyme that loves the green hill's breast," were greeted by odours that I will not describe, and which I heartily hope my readers cannot imagine; our feet, that on leaving the city had expected to press the flowery sod, literally got entangled in pigs' tails and jaw-bones; and thus the prettiest walk in the neighbourhood was interdicted for ever.*

The common breed may for the most part be described as large, rough, long-nosed, big-boned, thin-backed, slab-sided, long-legged, ravenous, ugly animals. But latterly great improvements have been made in it by judicious crossing with the Chinese and Berkshire pigs, by crossing these two breeds with each other, and by careful breeding from these two stocks without intermixture.†

Mr. Bement, of Albany, who has devoted great attention to the rearing and breeding of swine, speaks in the highest terms of praise of the cross between the pure Chinese breed and the original breed of the country, or, "*land-shads*," as he termed them. He says that the Chinese breed was first introduced about twenty years ago, but that from their size seldom attaining more than 250 lbs., and from their delicacy, they were not adapted for "a farmer's hog." But with the just-mentioned cross they become all that could be wished. He thus describes the "improved China hogs:"—"In colour they are various—white, black and white, spotted, and gray and white; they are longer in the body than the pure Chinese breed; small in the head and legs; broad in the back; round in the body; the hams well let down; skin thin; and flesh delicate and finely flavoured. They are easy keepers, small consumers, quiet in disposition, not given to roam or commit depredations; and when in condition may be maintained so upon grass only."‡

The best Berkshire breeds as imported into America vary somewhat in size and appearance; that from which most of the present stock have

* Domestic Manners of the Americans.

† AMERICAN PIGS.—In the 15th annual Fair in New York, the following account was given of the Pigs:—"The swine were fairly represented in the Berkshires, Chinas, and their crosses. There were some beautiful specimens of these, and if any one doubts that it is the corn-crib alone that makes the pork, let him scan closely the fine forms, thin hair, mellow elastic handling, delicate limbs, and quiet countenance, expressive of pence with all the world, exhibited by some of the grunTERS inside the yard, and their Ham-mish kindred without, a roaming, restless, thriftless brute, with legs reaching to the back-bone, the bristles of a porcupine, the hide of a rhinoceros, the snout of a plough-share, and all the grim aspect and unthrifty look of a wolf or hyena; thrice cursing the human race—a curse to their neighbours, a curse to their feeders, and a curse to their eaters."—*New York Herald*.

‡ The Cultivator, vol. ii.

been raised was taken to America in 1832. This breed has spread rapidly over the country, and fetches a high price from its peculiar aptitude to fatten. Its prevailing characteristics are—a fine head, a dished face, rather upright ears, close shoulders and hams, and a short body; animals of this kind mature very rapidly; and produce most delicate meat.

A celebrated pig-breeder says—"The Americans are so partial to this breed, that I have sold sucking-pigs weighing from 30 to 32 lbs. each, when seven or eight weeks old, at 50 dollars for a sow pig, and 30 dollars for a boar. I sold a sow pig of eight weeks old for 70 dollars. I knew a pair of pigs of this breed, killed at the age of one year and a quarter, which weighed 41 stone; thus the pig's age being 456 days, and his weight 574 lbs., he must have increased at the rate of rather more than 1½ lb. per day."* This breed is to be found in New Orleans, Kentucky, Alabama, Albany, Saratoga, Newburn, &c. There are now various improved breeds, known for the most part under the names of the improvers, or of the localities in which they are found, arising from crosses of the original American hog with the above-mentioned breeds, or others which may have been imported from England and other countries. The establishment of agricultural societies and cattle-shows has contributed in the New as well as in the Old World to direct the attention of farmers and breeders to all kinds of domesticated animals, and the advantages which have been obtained in swine alone are sufficiently great to prove incentives to increased care and study on the all-important principles of breeding.

Head, in his journey from Halifax to Upper Canada, again and again alludes to the fine pigs he saw, and the delicious pork with which he was regaled by the settlers he met with in various parts. He says that bears are very fond of pork, for they often get into the farm-yards and carry off a squeaking struggling victim to regale themselves upon.

CANADA.

In Canada the breed of swine furnishes the principal supply for food and exportation; great quantities of pork being sent to New Orleans. Mr. Owen has established a whiskey distillery, and fattens the swine on the refuse. About 1500 barrels of whiskey, worth 10 dollars a barrel, were made every year in Mr. Owen's distillery. Great numbers of swine roam in the woods of Indiana, far from all human dwellings, where they grow very fat upon the abundance of oak and beech mast.† They are of a reddish-brown colour, with round black spots; there are some quite wild, which any body is at liberty to shoot. These animals are never housed, even in the vicinity of Harmony. In the depth of winter the young ones often perish with cold, or are devoured by the mothers; and then dead swine will be seen lying about in all directions, some partly devoured by others. The negligence and want of feeling with which these animals are treated is very great, and consequently they can never be expected to prosper or yield those advantages which might be derived from them under proper treatment.‡

* The Cultivator, vol. ii.

† In some parts where great numbers of swine are allowed to run almost wild, a triangular yoke is fixed round their necks to prevent them from breaking through fences.—Weld's Travels in North America.

‡ Maximilian's Travels in North America.

OHIO.

Professor Silliman, in his account of Ohio, says that large numbers of hogs pass the winter in the woods quite independent of the assistance of man, subsisting on nuts and acorns. Single individuals of these are occasionally destroyed by bears and wolves, but a herd of ten or twenty hogs are more than a match for a wolf or panther. Indeed an old hunter once saw a panther spring from a tree into a drove of wood hogs, and scarcely had he touched the ground than the larger ones fell upon him with their tusks and the weight of their bodies, and killed and tore him in pieces in a few moments.*

MEXICO.

In Mexico fine breeds of pigs are kept by many persons of wealth as an article of trade as well as of consumption, and the greatest possible care and attention are paid to the cleanliness and comfort of these animals; nay more, the Mexican pigs may be said to possess the luxuries of life, for two Indian lads are kept to sing the grunting herd to sleep. These boys are chosen for the strength of their lungs and their taste and judgment in delighting the ears and lulling the senses of the porcine harmonists, and they take it by turns to chant throughout the whole day; nor does their performance appear to be unappreciated by their strange audience, but rather to afford exceeding delight and gratification.†

HEBRIDES.

The New Hebrides, the Marquesas, the Friendly and Society Islands, and New Guinea, abound with a breed of swine closely resembling the Chinese, and these being almost the only domestic animals which the natives of these islands possess, they accordingly receive great care and attention. This race is small, the belly hanging, the legs short, the tail almost imperceptible, and the colour gray. Its flesh is very white and delicate.

COLUMBIA.

In the woods of Columbia there are numbers of swine, but for the most part wild; and the flesh of these wild ones is far superior to that of the few that are domesticated, as that of the latter, from the animals being often fed on stale fish and all kinds of abominations, acquires a rancid and unpleasant flavour. Some of the settlers chiefly live by the sale of the flesh of wild swine, which they obtain by hunting, and then cure or dry it.

Experienced hunters will kill their fourteen or fifteen swine a-day, and a well trained dog will often destroy two or three of these animals a-day by himself. The mode of proceeding is for the dog to keep the hog at bay while the hunter creeps up, and watching his opportunity, throws his lance with such vigour as to pin the animal to the ground. This done, he rushes upon him, seizes the lance firmly with one hand, and with the other dispatches the game with his knife.‡

* Arcana of Science, 1828.

† Bullock's Mexico.

‡ Cochrane's Columbia.

In Paraguay and Brazil swine are likewise abundant, and for the most part wild.

The Falkland Islands were stocked with swine by the French and Spaniards, but little, if any, trace of the original breeds can now be discovered in the fierce, bristly, tusked animals now found there, some of the older ones of which rival the grisly boar in appearance and wildness.

SOUTH-SEA ISLANDS.

The South-Sea Islands, on their discovery by Europeans, were found to be well stocked with a small, black, short-legged hog; the traditional belief of the human natives was, that these animals were as anciently descended as themselves. The hog, in fact, is in these islands the principal quadruped, and is of all others the most carefully cultivated. The bread-fruit tree, either in the form of a sour paste or in its natural condition, constitutes its favourite food, and its additional choice of yams, eddoes, and other nutritive vegetables, renders its flesh most juicy and delicious; its fat, though rich, being at the same time (so says Foster) not less delicate and agreeable than the finest butter. Before our missionary labours had proved so signally successful in these once forlorn and benighted regions, by substituting the mild spirit of Christianity for the sanguinary forms of a delusive and degrading worship, the Otaheitans and other South-Sea Islanders were in the habit of presenting roasted pigs at the *morais*, as the most savoury and acceptable offering to their deities which they could bestow.

ASIA.

Throughout the greater part of Asia swine are to be found. The extensive and magnificent forests which cover much of the Birmese Empire, Siam, Cochin China, and other kingdoms of the south-east, abound with hogs, as well as other pachydermatous animals.

Here are found the celebrated Siamese or Chinese breed, so much esteemed throughout all parts of the world to which they have been exported: distinguished for their small size, fine head and snout, compact deep carcass, large hams and shoulders, short limbs, delicate feet, fine hair and skin, aptitude to fatten and grow, and the sweet delicate meat they yield.

CHINA AND JAPAN.

The Chinese and Japanese are great pig-breeders, and make the art of crossing, breeding, and rearing swine, which furnish them with their principal animal food, an object of peculiar attention and study. Merchants who have resided for some time in China, and even travellers who have merely been able to bestow a superficial glance on matters, speak of the great care bestowed on this point; but no author appears to have given any details as to the course of practice adopted. Perhaps from the naturally jealous and uncommunicative disposition of the Chinese, they have been unable to acquire any; and, perhaps, few have thought it worth while to trouble themselves about so degraded an animal as the pig. However this may be, it is much to be regretted that

the information is so very scanty, for many valuable hints might probably have been thus obtained.

Tradescant Lay, the naturalist in Beechey's expedition, in his interesting work on China, thus amusingly speaks of the natives and their swine:—"There is a striking analogy between these two. A Chinese admires a round face and the smooth curvatures of a tun-belly, and where opportunity serves, cultivates these additions to personal beauty in himself. The Chinese pig is fashioned on the same model. At an early period the back becomes convex, the belly protuberant, and the visage shows a remarkable disposition to rotundity. Nor is the resemblance merely personal; in the moral character there is an amusing similitude, contrariety and obstinacy being the prevailing characteristics of both men and brutes."

This same author informs us that swine are rarely driven or made to walk in China, but conveyed from place to place in a species of cradle suspended upon a pole, carried by two men. But he says, "the difficulty is to get the animal into this conveyance, and this is accomplished by the cradle being placed in front of the pig, and the owner then vigorously pulling at 'porky's tail,' and in the spirit of opposition the animal darts into the place they have prepared for him. At the journey's end the bearers dislodge him by spitting in his face."

Mr. Lay states that "pork is very plentiful in China, but never agreeable to the European eye, from its shining flabby appearance; it does not taste either like our pork, and is only tolerable when cut into thin slices and fried in soy to correct the grossness of the natural juices. The natives cut it in long slices or rashers, and dry it in the sun, and thus prepared it is not unpleasant in flavour, although it is then by no means easy to distinguish it from dogs' or cats' flesh similarly prepared."*

CEYLON.

In speaking of Ceylon and its neighbourhood, an intelligent traveller says:—"The swine here are a long-legged ugly breed, allowed to run wild and pick up whatever food they can get. I never saw at any native cottage or farm a pig penned or put up to fatten, and yet the natives are very fond of hog's flesh, and never hold any feast or festival without this meat constituting the chief and most approved dishes."

HINDOSTAN.

The existence of a breed of swine in Hindostan and the Birmese empire is mentioned by several travellers, but scarcely one gives any account of them. It would seem, however, that they are identical with the Siamese breed. Hogs are also enumerated as among the wild beasts of Central India. Some of the Hindoo tribes use hog's blood for all the purposes to which other nations apply holy-water; but pork is not eaten, excepting by Europeans and the lowest caste of Hindoos. In the Eastern Archipelago and the Moluccas, a breed of wild swine exists bearing great resemblance to the Chinese, but rather longer in the legs and lighter in the body, and affording delicious meat.

* The Chinese as they are, by Tradescant Lay.

TURKEY AND ARASIA.

In Turkey, Syria, Persia, Arabia, and the north-eastern parts of Asia, comparatively few pigs are found, and these are of an iron-gray, black, and occasionally brown hue; short-legged, small, round in the body, very apt to fatten, and attaining the weight of from 350 to 400 lbs. And there are two ways of accounting for this, viz.: the prevalence of the Mohammedan religion, and the sandy open nature of the country; for it is chiefly in well-wooded if not cultivated districts that we find swine, their nature and habits alike unfitting them for dry sandy deserts.

AFRICA.

In this quarter of the globe again we meet with but few swine, until we approach the south-eastern parts, and for the same reason which we have just given. In Abyssinia they are to be found, but they are not held in much estimation. They have been imported into New Holland, Caffraria, and the Cape of Good Hope, but are not kept to any extent, on account of the difficulty of feeding them. In most of these places pork is chiefly used as food for the lower classes, and but little care or attention is bestowed upon the animals; and the breeds greatly resemble the Chinese variety, but are somewhat less, being short-legged, round bodied animals, of a black or dark brown colour, the bristles few and almost as fine as hairs, and the tail terminated by a tuft.

The Coast of Guinea used to possess a breed of swine which have been exported thence as an article of commerce, especially to the new settlements in America and to some parts of the East Indies, and were held in high estimation at that time. But the cessation of the intercourse induced by the slave-trade, and the discovery of more valuable breeds, have rendered these almost forgotten. These animals were large in size, square in form, of a reddish colour, the body covered with short bristly hair, and smoother and more shiny than almost any other variety of the porcine race; the tail very long, and the ears long, narrow, and terminating in a point. This variety is also found in Brazil.

EUROPE.

We now find swine almost universal, and every where, more or less, an object of special care and attention, both as furnishing a valuable kind of animal food and an article of commerce.

MALTA.

Coming up the Mediterranean Sea we find the small black Maltese breed, the bodies of which are almost bare and smooth, and which fatten so aptly and afford such delicate pork. Spain then offers its breeds, none of which are, however, held in great estimation out of their native country. The chief of these is a short-headed, long, yet round-bodied, dumpty-legged variety, of a reddish brown or copper colour; the skin fine and the bristles slender; it is small in size, very prolific, and may easily be fattened to an enormous weight. This breed is also found in Portugal and some parts of the south of Italy; it closely resembles the

Siamese pigs, and has doubtless originally sprung from them. The far-famed Bologna sausages are made from the flesh of this animal.

ITALY.

Italy too is in some degree celebrated for its pigs, the best breeds of which, like the Maltese, are small, black, destitute of bristles, and delicate in flesh. The Neapolitan breed has been extensively exported, for the purpose of crossing with other kinds, and has found considerable favour in many parts of England. In themselves these pigs are not sufficiently hardy for general use, but, crossed with rougher breeds, they yield a valuable progeny, fine in form, delicate in flesh, and easy to fatten. There is a much larger race of swine bred in the Duchy of Parma, and generally considered to be the finest breed in Italy, in every point of view.

In Palermo, Bosco, the environs of Rome, and the neighbourhood of Bologna, Count Chateauvieux tells us pigs are kept. Those at Bosco, on the Apennines; he describes as a good breed, which the farmers fatten on chestnuts and milk, housing them in the winter and suffering them to run over the mountains during the summer. At the farm of Campo Morto he found a herd of 2000 pigs, of the domestic breed, and black. They run all the year on the immense tract of land which extends towards the sea, are fattened on nuts and acorns, and yield excellent meat. They are not indigenous, but have been brought thither to stock the woods, and they are regarded by the proprietor of that farm as the most valuable part of his stock, for their keep costs him little or nothing, and they yield a very good profit.

The pigs he found on the marshy plains of Polesino, between Bologna and Ferrara, he describes as large, lean, thin-flanked, and long-limbed animals.*

In some of the towns of Italy certain swine are made privileged animals, by undergoing some ceremonies; they are then, to all intents and purposes, citizens, and may roam the streets unmolested seeking their daily food. Among the ancient statutes of Trieste, some of which are now abrogated, the following may still be found:—"It shall be also lawful for two pigs of the fraternity of St. Anthony to wander in the city, they having one ear cut off and the other slit. But when they have pro-created, the superior or stewards of the said fraternity shall provide that all the young ones, except two only, be within the month next ensuing, sold or sent out of the city, under a penalty of 50 livres. And if the said two pigs do any damage, the stewards shall be bound to make it good, and the party complaining shall be delivered on his oath, both as to the nature of the damage and its extent. And to every judge of the city it shall be lawful to hear and determine all such causes in a summary way, after one sole citation of the stewards."

GERMANY.

Pursuing our way to Germany we meet with totally different animals, submitted for the most part to an entirely different management. The common breeds of the country are every where described as huge,

* Chateauvieux's Letters from Italy.

gaunt, long-legged, lean-bodied, greyhound-like animals, with exceedingly long snouts and coarse bristles, forming almost as much of a mane on the neck and shoulders as those of the wild boar.

In Prussia and many parts of Poland a rather smaller, but scarcely less uncouth, race are met with, of a yellow or reddish brown colour.

Thäer, in his valuable work on agriculture, informs us, that "the chief breeds of pigs known in the north of Germany, and crossed in various different ways, are,—the Moldavian, Wallachian, and Bothnian pigs, remarkable for their enormous size, iron-gray colour, and large lapping ears; and the Polish, or, properly speaking, the Podolian pigs, which are also very large, but are of a yellow colour, and have a broad brown stripe along the spine." These two breeds, he says, furnish the large pigs for fattening, but they require a proportionably large quantity of food, and besides are not very productive, the sows seldom bringing forth more than four or five at the most at a birth.

The Bavarian pigs, he states, are much esteemed for their smallness of bone and aptitude to fatten; but the flesh is not liked, it being too flabby and soft. This breed is usually marked with reddish brown spots.

The Westphalian is another breed very generally met with; these animals are large in size and very prolific, bringing forth ten or twelve at a litter.

The next variety mentioned he designates "the English pig," and describes it as being large, full, and deep in the body, and requiring very substantial food. A cross between this breed and the Westphalian is stated to produce an excellent animal.

To these he adds the Chinese breed, the Spanish or African black pig, which he estimates very highly from its aptitude to fatten on indifferent or scanty food, its rapid growth, delicate flesh, excellent hams, and the advantages derived from crossing the larger breeds with it; and lastly, the German pig, properly so called. But it appears that this can scarcely be regarded as a distinct breed, but rather as the result of numerous and various crosses, for he says: "This breed is different in its characteristics in different provinces; the colour is white, black, gray, or spotted. It is of a middling size and can be supported on a moderate quantity of nourishment. There is no doubt but that by more attention being bestowed upon the breeding, rearing, and feeding of this race, they might be materially improved, but most of the persons who undertake the management of pigs on an extensive scale, seem rather anxious to try the effect of different and new crosses than to improve the old breed."*

HUNGARY.

In Hungary, Croatia, and Servia a race of swine resembling that found in Turkey are met with; small, of a dark gray colour, and short-legged, yet not apparently deriving their origin from the Chinese. The flesh of the swine reared in Servia is said to be more delicate than will be met with any where throughout the whole of Europe.

In Poland, Russia, Sweden, and the northern parts of Europe, the swine yet retain all the characteristics of their ancestor the wild boar.

* Thäer's Principles of Agriculture, Transl. by Messrs. Johnston and Shaw.

They are mostly of a red, or dirty brown, or yellow colour; long in the body, light and active in make, having long legs, a broad flat head, erect ears, and a nervous slightly up-turned snout. They are wild in their habits, fierce, not apt fatteners, or producing delicate meat.

In Holland and Belgium we find numerous varieties and crosses, but the original breeds have large bodies and long lopping ears; the sows are prolific, and if properly attended to, the animals fatten very kindly. There is a variety often met with,—and much esteemed for its productive powers, its disposition to fatten, and the delicacy of its flesh,—which most probably derives its origin from a cross between a native pig and one of the Siamese breed. This animal is of a medium size, rather short on the legs, with a full round body, straight back, broad flanks, and small head. The bristles are white and thinly scattered over the back, but growing rather closer upon the neck and towards the head.

FRANCE.

The original breeds of France are almost all coarse ungainly animals, for the most part white, excepting towards the south, and there we find the native breeds very much to resemble those of Italy. “In the time of Buffon the greater proportion of the hogs in the north of France were white, as were likewise those of Vivarais; while in Dauphiny, which is not far distant, they were all black. Those of Languedoc and Provence were also of the latter colour. Black pigs still prevail both in Italy and Spain. According to the great French naturalist, one of the most evident marks of degeneration (an ill-applied term) is furnished by the ears, which become more supple and pendent as the animal changes into the domestic state. He regards the wild boar as the model of the species, and I think erroneously, for it can only be looked upon as formed on the model best adapted to the haunts and habits of a wild animal, the welfare of which requires either the instinct of a cunning concealment or the possession of strength or swiftness. Now concealment in a pigsty is of little avail when the day of terror comes, and the obesity of a well-fed porker is, and must ever continue, entirely inconsistent either with speed of foot or vigour of limb; therefore the proper attributes of the animal in its unreclaimed and domesticated conditions being incompatible with each other, those of the former ought not in any way to be set up or assumed as a model by which the latter should be altered or improved.”* Of late years French agriculturists have seen the advantages small breeds possess over large ones, and endeavoured by judicious crosses to reduce the size of their pigs, and at the same time give to the breeds all the value arising from early maturity, a kindly disposition, and productiveness. M. Magne says, “Our breeds of pigs are in general very defective; they are long-limbed, thin-necked, narrow-chested, and have high curved backs; they are hardy, but far from precocious, fatten with difficulty, and consume an immense quantity of food compared with the flesh they yield.”†

We are partly indebted to Mr. Wilson’s valuable ‘Essay on Domestic Animals’ for the following account of the present chief breeds

* Quarterly Journal of Agriculture, vol. iii.

† Traité sur l’Elève, Entretien et Engraissement du Porc.

of swine in France. The most distinguishable of the present races of France are the following:—

“1. *The race of the Pays d’Auge* (by some authors called the Normandy breed,) which has the head small and sharp-pointed; the ears narrow and pointed; the body lengthened; the legs broad and strong; the hair coarse, spare, and of a white colour; and the bones small. It attains to the weight of 600 lbs.” M. Bella considers that this breed are great eaters, but do not fatten kindly.

2. *The race of Poitou*, of which the head is long and thick, the point projecting; the ears large and pendulous; the body lengthened; the bristles white and coarse; the feet broad and strong; and the bones large. Its weight does not exceed 500 lbs.

3. *The race of Périgord*, of which the neck is thick and short, the body broad and compact, and the hair black, short, and rough. This race, when crossed with the Poitou pigs, produces very good animals; and it is probable that the pied swine, so common in the south of France, are descended from this cross.

4. *The race of Boulogne*. Of considerable dimensions, and well inclined to fatten quickly; ears very broad; general colour white. This breed has sprung from a cross between the large English breed and one of the common races of France.

Of other continental races we shall mention the *Jutland swine*. Of these the ears are large and pendent, the body elongated, the back somewhat curved, the legs long. The size of this breed is considerable, as from 200 lbs. to 300 lbs. (French livres) of lard are got from them in their second year. They form an important branch of commerce.

The race known abroad under the name of *Cochon de Siam* is the representative of our Chinese breed. Its ears are short, straight, and flexible; its body is covered with soft and somewhat silky hair, which is stiff and thick on the head and back of the neck, and frizzly on the cheeks and under-jaw; on the other parts it is thin, and for the most part hard and black. The skin is also black, except on the belly; the eyes are surrounded by a slight tinge of flame-colour; their tails measure nine inches in length; their bodies three feet three inches; their height at the shoulder is one foot eight inches (French.) This breed appears to have spread extensively over most of the southern shores of the old continent.*

To these he adds the Turkish hog, the New Guinea hog, De Witt’s hog, and the smooth or short-legged swine, the two latter of which evidently derive their origin from a cross with the Siamese and some other breed, and all of which fatten easily and to a great weight, and are good breeders.

The swine in Normandy are, even to the present day, of the large gaunt grizzly race, common in some of the south-eastern counties of England and Germany.† Mr. Wilson informs us, that, in the time of Buffon, by far the greater proportion of the swine in the north of France were perfectly white, as were also those of Vivarais; while in Dauphiny, which is not far distant, they were all black. Those of Languedoc and Provence were likewise black. This is a curious fact, and seems to

* Quarterly Journal of Agriculture, vol. iii. p. 48.

† Mr. Lorimer, in his Tour through Normandy in 1845, describes the pigs to be of that grayhound-like variety so common all over the Continent.

prove, beyond a doubt, that the parent stock of these two opposite colours was totally different, and also that there was little intermixture or crossing among the breeds of these places, but that the races were preserved pure and distinct. He also mentions that latterly a new variety of the porcine race has been introduced under the name of "*Le Porc de Nobles*," which appears to have been derived from the improved English breed, which originated from a cross between an Anglo-Chinese sow, and an emancipated American boar. This answers very well, and is much esteemed on account of the delicate flavour of its flesh.

In Champagne the breed of pigs are white, long-limbed, flat-sided, hollow in the flanks, and having large ears.

In Quercy the breed is of a moderate size, has a small short head, little ears, and a curved back; most of these pigs are spotted, but there is more of black than white in them.*

In the department of Mayenne, and along the Oudon, some very valuable kinds are found, which have been carefully bred and reared expressly for the purpose of improving the French breeds of pigs. There are two distinct varieties, the one called the "Craon Breed," which has a long body, short legs, and a back so broad that even when the animals are lean the spine does not project. These fatten well and easily, but do not begin to make much flesh until they are eleven or twelve months old, after which they rapidly develop themselves, and attain an immense weight.

The other variety is designated the "Valley Breed:" here, too, the legs are short, the body of a medium length, the back extremely broad, the ears large and falling to the tip of the snout, which is short and wide; the back is covered with bristles, the tail finished with a tuft of the same, and from the under-jaw two hairy appendages similar to those of a goat depend. Pigs of this breed fatten well, and may be killed at any age.†

In the province of Bresse, in the neighbourhood of Lyons, of the Dombes, and Carolais, and prevalent through the department of Aisne, is a breed called the Bressane race. These animals are of a moderate size, long in the body, round in form, short-legged, with long pendulous ears, and of a dark or blackish colour, with a broad stripe of white encircling the body; their flesh is delicate, and of a fine flavour.‡

An attempt was made to introduce some of the English breed of swine into France by a young agriculturist, and he thus narrates the results:—"I began with the large Shropshire pigs. They pleased my eye, and for some little time I was perfectly satisfied; but presently I began to remark, that, although they devoured an amazing quantity of food, they fattened but very slowly, and seemed to derive no advantage whatever from the herbage and vegetables which they found in the fields.

"When killed, the flesh, and especially the fat, was exceedingly coarse. The sows, nevertheless, yielded many pigs at each farrow, which, from their size when young, sold well to persons who were tolerably rich, and knew little or nothing about the breeding of pigs.

"I next tried the small Berkshire pigs, and immediately perceived a

* M. Magne, *Traité du Porc*.

† *Revue Agricole* de Juillet, 1840.

‡ M. Magne, *Traité du Porc*.

very sensible improvement. They fattened quickly, procured most of their nourishment from the fields, and their flesh was very superior to that of the last-named breed. But as they were large, I thought to effect a still greater improvement by exchanging them for the Chinese; but here I fell into the opposite extreme. The Chinese were prolific, fattened speedily, and almost obtained their own subsistence; but they were faulty in form, their flesh was not firm, but loose in fibre, as if they had died of disease.* And, accordingly, the experimenter returned to some of his best native breeds.*

In **FLANDERS** and the **NETHERLANDS** the indigenous swine are long-legged, narrow-backed, flat-sided, ugly, gaunt animals, difficult to fatten; but when in good condition making fine-flavoured, excellent pork and bacon.

THE CHANNEL ISLANDS.

JERSEY.—Great attention has here been paid to the breed of pigs, which have improved by crosses and admixture with the best English and French varieties. The pork is excellent; many declare it to be finer and more delicate in flavour than any English pork. It forms one of the chief articles of consumption during the winter months, and sells at from 4*d.* to 5*d.* the pound.

GUERNSEY.—The swine here have latterly been considerably improved by the exertions and encouragements of the Guernsey Agricultural Society. The original breed resembled the native French and Irish pigs, and were large, coarse, ungainly, and unprofitable, evidently descended from the wild long-legged, flat-sided race; but judicious crosses with the Hampshire and Berkshire breeds have now made it a well-shaped, profitable animal. The Guernsey pigs of the present day fatten readily and cheaply, and often attain to an enormous size. One was killed not long since weighing 640 pounds (80 stone, Smithfield weight,) offal not included. The flesh sold at 4½*d.* per pound, Guernsey weight, which is ten ounces heavier than an English pound. The pig here forms part the establishment of every cottager, and is kept a close prisoner in his sty, where he is well supplied with buttermilk, bran, potatoes, cabbages, and all kinds of vegetables during the spring and summer, and fed almost exclusively on parsnips from September. They are generally killed at about twenty months old, and weigh then from 300 to 400 or 450 pounds.† Pork forms the staple food of the Guernsey farmers and cottagers.

SERK.—The swine here are very similar to those of Guernsey; if there is any difference, it is that they are somewhat larger. They are managed in a similar manner, fatten well, and are profitable animals.

ALDERNEY.—Here, too, the original large breed have been improved by judicious crosses. The fat hogs reach an enormous size, sometimes even outweighing a tolerably fed cow; but 500 pounds is no uncommon weight.‡

The ISLE OF MAN.—Here the original breed of swine are small, wild, apt to fatten, and that without much care or attention, and yielding ex-

* *Annales d'Agriculture Française*, Numéro 29.

† The author has here to acknowledge his obligation to Colonel Lake, of Woodlands, Guernsey, for the information so kindly contributed by him.

‡ See *Inglish's Channel Islands*.

cellent meat. Crosses have been introduced, which perhaps have better adapted the animals to the system of sty-feeding; but we question whether they can be said to be improved by having been rendered more dependent upon the care of man.

THE HEBRIDES, OR WESTERN ISLES.—The most common breeds of these islands are generally considered to be aboriginal, and lineally descended from the wild boar. These swine are described as being very small, active, and shaggy, of a grayish or dirty yellow colour, grazing wild upon the hills like sheep, their sole food herbage and roots, and receiving no other sustenance or shelter all the year round but what is furnished them by nature, yet being in good condition, and affording excellent meat. When artificially fed, and carefully sheltered and tended, they will attain to a very considerable bulk, without any deterioration of the quality and flavour of their flesh.*

THE SHETLAND ISLANDS.—The breed of swine here very much resemble those we have just been describing. They are small, of a dirty white or yellowish brown colour, remarkably strong in the snout, with sharp-pointed ears, and an arched back, from which rises a forest of stiff bristles. When poor, the flesh of these animals is coarse; but those which are properly fattened yield sweet and delicate meat, and the hams, when cured, are pronounced by connoisseurs to be excellent. The Shetland pigs are generally suffered to roam about and forage for themselves at will, and the mischief they do is by no means inconsiderable; for with their muscular snouts they plough up the soil, and root out potatoes, carrots, and turnips, and even upturn the growing corn.

Dr. Hibbert informs us that there is an ancient law in Shetland relative to these animals, viz. "that none have more swine than effeiring (proportional) to their land labouring;" and "that none have swine pasturing on their neighbours' lands, under the penalty of ten pounds besides damages." But he adds that these enactments are but little regarded; the pigs are allowed to wander where they please, and, far from being a source of profit, are, from the mischief they do, an absolute loss to the country.†

The same author describes the original Shetland pig as "a little brindled monster, the very epitome of a wild boar, yet scarcely larger in size than a terrier dog:—

"His bristled back a trench impaled appears,
And stands erected like a field of spears."

According to his account, "this lordling of the seat-holds and arable lands ranges undisturbed over his free demesnes, and, in quest of the earthworms and the roots of plants, furrows up the pastures or corn-fields in deep trenches, destroying in his progress all the plovers', curlews', and other birds' nests he meets with. He bivouacs in some potato-field, which he rarely quits until he has excavated a ditch large enough to bury within it a dozen fellow-commoners of his own weight and size. Nor is the reign of this petty tyrant wholly bloodless; young lambs just dropped often fall victims to his ferocity or thirst for blood."

* Walker's Hebrides.

† Dr. Hibbert's Account of the Shetland Isles.

THE ORKNEYS.—To describe the swine found here would be but a repetition of what we have already said. They are small, of roving habits, do much mischief, yield but poor meat unless carefully fattened, and seldom reach a weight of more than sixty or seventy pounds. Low informs us that the pork rarely fetches more than 2*d.* per pound, and a butcher never thinks of giving more than 4*s.* or 5*s.* a-head for the pigs. Ropes are fabricated from the bristles of these animals, by which the natives suspend themselves over the most fearful precipices in search of sea-fowls' eggs; and, short as the hair or bristles are, the ropes manufactured from them are said to answer better for this perilous purpose than hempen ones would, being less liable to be frayed by the sharp and rugged rocks.*

It is in these northern islands that several authors have spoken of swine being used as beasts of draught, but it could not have been these aboriginal and diminutive breeds, we should conceive, but some of the large heavy kinds imported from England or Ireland.

SCOTLAND.

THERE can be little doubt but that the aboriginal breed of Highland swine are, like those found in the Hebrides, descended from the wild boar, for, until within the last half-century, they retained much of the form, and many of the habits and characteristics, of the wild breed. They also are small, shaggy, bristled, and wild; wandering about the hills, grazing and seeking out roots and other favourite food, and requiring no care or sustenance at the hand of man, yet keeping in condition, and making excellent pork or bacon. The latter end of the autumn is the best time to kill them, as they are then in good flesh.

Those which have been brought into the low country and artificially fed, have fattened to a considerable size, and yielded fine-grained, firm, well-flavoured meat.

Formerly immense herds of these small swine were reared in the highlands of Scotland, and brought down to the lowland markets for sale; the practice of keeping these animals gradually declined some fifty or sixty years ago, but has latterly been revived since the cultivation of the potato has become more extensively practised. There cannot, however, be a doubt that a great number of this breed of pigs might be advantageously fattened upon every Highland farm where the land in crop is enclosed, both on account of the little artificial food they require, and the roots and various substances they will consume which no other kind of stock would touch.

* See *Fauna Orcadensis* by the Rev. Geo. Low.

But although the practice of keeping swine in the Highlands and north of Scotland is of very ancient date, there are no records which speak of their existence in the more southern parts of Caledonia; indeed, if we may give credence to several anecdotes related by Mr. Henderson,* they were absolutely unknown animals in several parts.

It would seem that, some hundred and twenty years since, a person residing in the parish of Ruthwell, in Dumfriesshire, received a present of a young pig, which is said to be the first which had ever appeared in that part of the country. This said pig strayed from his new home one day into the adjoining parish of Carlavroc, and wandering along the sea-side came upon a woman who was keeping cattle. She screamed at the sight of the "strange beast," and ran off to her village, and the pig after her. There she declared she had seen "the deil come out of the sea, and that he had chased her, roaring and gaping at her heels." One of the bravest of the villagers got a Bible and an old sword to "cunger the deil;" but while he was uttering his threats, along came the creature with such a loud "grumph," that the poor man fell down half dead with fright, and all the rest fled, and then from windows and house-tops peeped at the "monster," until one fellow cried out that it was "the gude man o' the brow's grumphy," and gradually the alarm subsided.

This same pig seems to have frightened many persons at different times, as did another which escaped by some means from a vessel which put into Glencaple Quay, just below Dumfriesshire, and was hunted as a wild beast, and at last slain with a pitchfork by a man, who was termed "stout-hearted Geordy" all the rest of his life for the performance of this valorous exploit.

In 1760 there was scarcely a parish in Dumfriesshire which could muster twenty swine, but within ten years of that time they gradually began to increase, and each farmer took to keeping one or two, and from 1775 to 1780 the trade became pretty considerable. This increase was chiefly owing to the exertions of Lord Graham, of Netherby, who encouraged the breeding and rearing of swine among his tenants by every means in his power, and was the chief institutor and supporter of a market at Longtown, in Cumberland, for the sale of swine and pork.

The next steps were the establishments of pig-markets in several other principal towns in the southern parts of Scotland, and small premiums offered on every market-day to the owners of the finest pig or the largest number of good swine brought to the market.

When thirty or forty years ago there was not a pig to be seen, as much as 400*l.* or 500*l.* worth of hogs and bacon, or pork, are now sold every market-day. This alteration is ascribed by some persons to the extension of the cultivation of the potato, and the consequent increased facility for feeding and fattening swine; but it may, doubtless, be also attributed to the increasing demand for animal food, the more extended views of farmers and agriculturists of the present day, and an appreciation of the profit and advantages arising from the keeping of these valuable animals.

There is a very good kind which are well made, white in colour,

* Henderson's Treatise on Breeding Swine.

have short upright ears, fatten quickly and on little food, and come early to maturity. Crosses with the Chinese have been tried, but they produce too delicate an animal, and consequently have fallen into disrepute. It would, however, be needless to enter into an account of all the varieties of swine now existing in Scotland, as, in describing the English breeds, we shall have to speak of all those which of late years have been introduced into Scotland, and either crossed with the original small, dark, prick-eared Scottish pig or with each other, or retained in their natural state. Henderson says that hundreds of pigs and *shots* (pigs from six to eight months old) are brought over from England every year, and fattened in Scotland.

ENGLAND.

The original breeds of this country are now rapidly losing all traces of individuality under the varied systems of crossing to which they are subjected. Formerly they might have been divided into two principal classes, the small and the large breeds: the former having ears tending to the upright, being dusky in hue, and greatly resembling the wild

THE OLD ENGLISH HOG.

boar in form; and the latter being long-bodied, long-eared animals, mostly white or spotted. The former were chiefly found in Scotland, and on the northern hills; and the latter in the lower and more midland counties of England, where the hog had been more domesticated.

Where individuals of the pure old breed are met with, they will be found long in limb, narrow in the back, which is somewhat curved,

low in the shoulders, and large in bone; in a word, uniting all those characteristics which are now deemed most objectionable, and totally devoid of any approach to symmetry. The form is uncouth, and the face long and almost hidden by the pendulous ears. They nevertheless have their good qualities, although aptitude to fatten does not rank among the number, for they consume a proportionally much larger quantity of food than they repay; but the females produce large litters, and are far better nurses than those of the smaller breeds. They are, however, now nearly extinct, disappearing before the present rage for diminishing the size of the hog and rendering his flesh more delicate; points which, however desirable to a certain extent, may easily be carried too far. Low judiciously observes: "While we should *improve* the larger breeds that are left us, by every means in our power, we ought to take care that we do not sacrifice them altogether. We should remember that an ample supply of pork is of immense importance to the support of the inhabitants of this country. England may one day have cause to regret that this over-refinement has been practised, and future improvers vainly exert themselves to recover those fine old races which the present breeders seem aiming to efface."

It would be vain to attempt to particularize the breeds of swine at present kept in this country, for they are daily altering their characteristics under the influence of some fresh cross; we will therefore content ourselves with enumerating those which are allowed to have been the chief and best breeds, and pointing out some of the alterations which have latterly taken place in them.

YORKSHIRE.

The old Yorkshire breed was one of the very large varieties, and one of the most unprofitable for a farmer, being greedy feeders, difficult to fatten, and unsound in constitution. They were of a dirty white or yellow colour, spotted with black, had long legs, flat sides, narrow backs, weak loins, and large bones. Their hair was short and wiry, and intermingled with numerous bristles about the head and neck, and their ears long. When full grown and fat they seldom weighed more than from 25 to 30 stone.

These have of late years been crossed with pigs of the new Leicester breed; and where the crossings have been judiciously managed and not carried too far, a fine race of deep-sided, short-legged, thin-haired animals have been obtained, fattening kindly, and rising to a weight of from 16 to 30 stone of 14 lbs. when killed between one and two years old, and when kept over two years reaching even 40 and 50 stone.

Mr. Samuel Wiley, of Bransby, to whose courtesy we are indebted for the information, and who has paid much attention to the breeding of swine, keeps only the pure improved Leicester breed, which with ordinary feeding will, at sixteen or eighteen months old, weigh from 18 to 20 stone of 14 lbs.; and, when put up to fatten, attain the weight of from 30 to 32 stone. He considers them far superior to, and more profitable than, the larger breeds.

Other breeders have crossed with the Chinese and Neapolitan breeds, and with some considerable success—the extremes of the large and small kinds happily correcting each other. The Berkshire pigs have

also been employed as a cross, and hardy, profitable, well-proportioned animal obtained. The original breed, in its purity, size, and defectiveness, is now hardly to be met with, having shared the fate of the other large old breeds, and given place to smaller and more symmetrical animals. Mr. Smith, of Hoyland Hall, Sheffield, whose kind replies to our queries we have to acknowledge, is another great pig-breeder, and his swine have carried off numerous prizes; they appear to be descended from a cross between the Yorkshire and Lord Western's improved Essex pigs. Their chief characteristics are—smallness of bone, great development of the fleshy parts, symmetry of form, and a strong propensity to fatten. Although hearty feeders, a small quantity of food suffices for them. When matured they readily attain the weight of from 30 to 35 stone of 14 lbs.

LINCOLNSHIRE.

The true Lincolnshire pigs are white, with long straight bodies, round carcasses, fine skins, and few bristles; the heads are well formed and of moderate size, and the ears erect, pointing somewhat forward and curling slightly at the tips; the hair is long and fine, but scanty. This breed was formerly considered as superior to any but the Berkshire in point of form and value, they being easily fattened, and the flesh being tender and of a fine flavour; with care they will reach 45 or 50 stone of 14 lbs. to the stone; and many, at a year and a-half old, will weigh 25 or 30 stone. They certainly do not attain to their maturity as early as some of the smaller breeds, but are, notwithstanding this, profitable animals, and good, sound, handsome stock. A cross between the Lincoln and Chinese pigs is productive of an animal presenting great tendency to fatten, and a small eater.

The old breed of this county are long-legged, narrow-backed, ungainly animals, with thick skins covered with short thick hair; the head is large, the forehead wide, and the ears set far apart. They are far from profitable animals, being enormous eaters, and fattening but poorly; few attain to a greater weight than 18 or 20 stone.

DERBYSHIRE.

Here there is no prevailing breed. The greater part of the pigs kept in this county come from Cheshire and Shropshire, and these are either left in their pure state, or crossed with some of the small English or foreign breeds, according as the taste or circumstances of the farmer or breeder leads him to prefer large or small animals.

LEICESTERSHIRE.

The old Leicestershire breed was a perfect type of the original hogs of the midland counties; large, ungainly, slab-sided animals, of a light colour and spotted with brown or black. The only good parts about them were their head and ears, which showed greater traces of breeding than any other parts. Mr. Bakewell improved them, and the variety thus obtained was called after him, and was superior in value and beauty to the old stock. Within the last few years various crosses have been tried, and the original breed is now fast losing all its peculiarities and defects.

BEDFORDSHIRE.

There is no distinct breed in this county; the animals are mostly Suffolk or Berkshire pigs, variously crossed. Some of the best kinds are distinguished for their aptitude to fatten early, and on a small quantity of food. His Royal Highness Prince Albert obtained a prize for some Bedfordshire pigs 41 weeks old, at the Smithfield Club Cattle-show in 1846.

ESSEX.

The Essex pigs, too, have been indebted for their improvement to crosses with the foreign breeds, and especially the Neapolitan, and with the Berkshire swine. They are mostly black and white, the head and hinder parts being black, and the back and belly white; have smaller heads than the Berkshire pigs, and long thin upright ears, short hair, a fine skin, good hind quarters, and a deep round carcass; they are also small-boned, and the flesh is delicate and well-flavoured. They produce large litters, but are bad nurses.

LORD WESTERN'S ESSEX BREED.

The most esteemed breeds are entirely black, and are distinguished by having small teat-like appendages of the skin depending from the upper part of the neck, which are commonly termed *wattles*. Some of these animals will attain the weight of 480 lbs., but they are not, according to some breeders, quick fatteners; while others prize them for their rapid growth and aptitude to lay on flesh, as well as for its excel-

lence; it forms small and delicately-flavoured pork. Lord Western has been the great improver of the Essex pigs, and his breed is highly esteemed throughout the kingdom.

Some Essex pigs, at only 23 weeks old, carried off one of the prizes at the Smithfield Club Cattle-show of 1846.

SUFFOLK.

The old pigs of this county are white in colour, long legged, long bodied, and narrow back, with broad foreheads, short hams, and an abundance of bristles. They are by no means profitable animals. Lord Western's improved Essex breed is much esteemed in Suffolk, and so are the Lincolnshire hogs.

A SUFFOLK GOAT, THE PROPERTY OF HIS LATE MAJESTY WILLIAM IV.

A cross between the Suffolk and Lincoln has produced a hardy animal, which fattens kindly, and will attain the weight of from 30 to 40 and even 50 stone of 14 pounds to the stone. Another cross, much approved by farmers, is that of the Suffolk and Berkshire. On the whole, there are few better breeds to be found in the kingdom, perhaps, than the improved Suffolk pigs; they are well-formed, compact, short-legged, hardy animals, equal in point of value to the best of the Essex, and superior in constitution, and consequently better adapted for general keep, and especially for the cottager. The greater part of the pigs at Prince Albert's farm, near Windsor, are of the improved Suffolk breed;

that is to say, the Suffolk crossed with the Berkshire and Chinese. They are small in size, with round bulky bodies, short legs, small heads, and fat cheeks. Those arising from the Berkshire and Suffolk are not so well shaped as those derived from the Chinese and Suffolk, being coarser, longer legged, and more prominent about the hips. They are mostly white, with thin fine hair; some few are spotted, and all easily kept in fine condition; they have a decided aptitude to fatten early, and are likewise valuable as store-pigs.

Many of the improved Suffolk breed will, at a year or fifteen months old, weigh from 12 to 15 or 16 score; at this age they make fine bacon hogs. The sucking pigs and porkers are also very delicate and delicious.

NORFOLK.

The pigs of this county do not materially differ from those of Lincolnshire, but are rather smaller. They, too, are white, fine boned, long eared, and well formed, good feeders, and yielding fine meat. This is especially the case in that part of the county which approaches Lincoln. Various breeds and varieties, are, however, to be met with in Norfolk, and among them some very inferior animals. There is a small variety resembling the Chinese, and probably descended from that breed, which is peculiar to this county, and much esteemed for its aptitude to fatten on a small quantity of food. A cross between the Norfolk and Suffolk pigs produces a fine hardy animal.

NORTHAMPTONSHIRE.

The old breed of Northamptonshire were large-bodied, large-boned, bristly animals, covered with white coarse hair. Their legs were short and their ears very long, so much so as often to trail upon the ground. They were capable of being fattened to a considerable size, but not without great trouble and expense. These gave place to a lighter-made animal, equally large, but with small bones, small ears, and greater aptitude to fatten. The Bakewell Leicester pigs are highly esteemed by some of the breeders and farmers of this county.

SHROPSHIRE.

This seems to have been only another variety of the Northamptonshire pigs; they are coarse, ungainly animals, with long heads, pendent ears, arched loins, large bones, flat sides, many bristles, and coarse wiry hair; they are brindled, or of a dirty white gray, or drab colour, with spots of black. They were capable of being fattened to a considerable size, and might be made at two years old to weigh 40 or 50 stone; but to accomplish this an abundance of food was required. They are by no means adapted for farm stock; but brewers, distillers, and those who have large quantities of refuse wash and grains, hold them in some estimation. Latterly the breed has been very much improved, and rendered more profitable, by crossing it with the Berkshire, Chinese, and other esteemed breeds, under the influence of which the most salient and objectionable points have disappeared, and the animals are now short legged, fine haired, straight backed, and thin skinned, white in colour, and weighing 14 or 15 stone at two years old. Lord Forester of

Willy Park, and Sir F. Lawly of Monkthopton, are in possession of the best breeds.

CHESHIRE.

The old breed of this county were some of the largest swine in England, standing from three and a half to four and a half feet high. They were black and white, white, and blue and white; long-bodied, narrow-backed, slab-sided, large-boned, long-limbed animals, having large heads, drooping ears of such a size as scarcely to permit them to see out of their eyes, and loose coarse-looking skins. Nevertheless they fatten to an enormous weight, and without consuming a comparatively larger amount of food than many of the much more esteemed English breeds. One excellent variety has been obtained by a cross with a Berkshire boar.

Of late years, however, the old Cheshire breed has almost entirely disappeared, and been replaced by a fine-boned, round-bodied animal, longer from head to tail and wider across the shoulders, coming earlier to maturity and easily fatten; the form of the head, too, is improved, and the ears are smaller and more shapely. These animals are chiefly derived from the old Berkshire and Cheshire breeds with an occasional and judicious cross with the Chinese. There is, too, a slight admixture here and there of the Leicestershire blood. They never attain to the size or weight of the old breeds, but their forms are more compact, their flesh finer grained, and their bones smaller. They are considered by many persons to be equal in value in all points to any breed in Europe.

GLOUCESTERSHIRE.

The Gloucestershire is another of the large old breeds, gaunt, long-legged, and unprofitable, of a dirty white colour, and having *wattles* depending from the neck. It has been supposed to have once been the prevailing breed in England, but is now rapidly disappearing before the alterations produced by the present prevailing system of crossing from small breeds.

HEREFORDSHIRE.

The pigs of this county are of the large class, similar in many respects to the Shropshire swine, and in all probability produced by a cross between those and some one or more of the smaller breeds; for they are smaller, finer-boned animals than the Shropshire pigs, have better shaped heads and ears, are more compact in form, and have greater aptitude for fattening. They may, in fact, be fed to an enormous size; and with proper management will, at two years old, weigh two or three times as much as most hogs of other breeds at the same age. No farmer need wish to possess finer and more profitable animals than may be found among the Herefordshire pigs; the bacon made of their flesh yields in excellence to none.

Latterly this breed has been crossed with the Berkshire, and the result has been a fine useful animal possessing numerous good points, but not much superior to the good old stock.

WILTSHIRE.

Here the old breed was one of the larger class. The Wiltshire swine were long in the body, round in carcass, hollow about the shoulders, and high on the rump; short-legged, large-boned, light-coloured, and the ears were large and pointed. They were, like most of this kind of pigs, large eaters and slow to fatten; but when fat attained a fair average weight, and their flesh was fine-grained and highly esteemed, especially as bacon. Crosses with the Chinese and Neapolitan breeds have however much improved the original race; they are now smaller boned, not so large in size, and fatten earlier and more readily.

CORNWALL.

The CORNISH BREED.—Here, again, the march of improvement is decidedly evident; the old Cornish hog, a large, white, long-sided, heavy-boned, razor-backed animal, possessing but little aptitude to fatten, is nearly extinct; and in its place we see a compact well-made pig, fattening kindly, coming early to maturity, and yielding in excellence and value to few. This variety has been produced by crossing the old breed with the Berkshire, Chinese, Essex, Leicester, and Neapolitan pigs. These animals require little food beyond vegetables and the farm house wash, excepting at the period of fattening, when about 24 gallons of barley will suffice to bring them, at nine months old, to the weight of from 350 to 400 pounds.

BERKSHIRE.

The Berkshire pigs belong to the large class, and are distinguished by their colour, which is a sandy or whitish brown, spotted regularly with dark brown or black spots, and by their having no bristles. The hair is long, thin, somewhat curly, and looks rough; the ears are fringed with long hair round the outer edge, which gives them a ragged or feathery appearance; the body is thick, compact, and well formed; the legs short, the sides broad, the head well set on, the snout short, the jowl thick, the ears erect, the skin exceedingly thin in texture, the flesh firm and well flavoured, and the bacon very superior. This breed of pigs has been generally considered to be one of the best in England, on account of its smallness of bone, early maturity, aptitude to fatten on little food, hardihood, and the females being such good breeders. Although termed the Berkshire breed, these pigs have been reared in various parts of the kingdom; and some of the very best have come from Staffordshire, from the progeny of the celebrated *Tamworth boar*. In Leicestershire also is a very fine race of them, descending from the stock of Richard Astley, Esq., who devoted much care to the improvement of the Berkshire pigs. Hogs of the pure original breed have been known to attain to an immense size, and weigh as much as 100 and 120 stone of eight pounds the stone.

One bred at Petworth measured seven feet seven inches from the tip of his snout to the root of his tail, and seven feet ten inches in girth round the centre; five feet round the neck, ten inches round the thinnest part of the hind leg, and two feet across the widest part of the back. He stood three feet nine inches high; and, what was most remarkable

in this monstrous animal, he did not consume more than two bushels and six gallons of ground oats, peas, and barley, per week.

Parkinson, in his "Live stock," vol. ii., gives some extraordinary accounts of the size and weight attained by individuals of this breed, and the profit yielded by them, and also of their aptitude to fatten at grass.

They are not, however, generally of an enormous size, being much smaller than several of the older breeds; their ordinary weight averages from 12 to 15 score, and some will at two years old weigh 20 score.

THE BERKSHIRE SOW, THE PROPERTY OF THE LATE DUKE OF BEDFORD.

It would be impossible to give an account of the numerous crosses from this breed; the principal foreign ones are those with the Chinese and Neapolitan swine, made with the view of decreasing the size of the animal, and improving the flavour of the flesh, and rendering it more delicate; and the animals thus obtained are superior to almost any others in their aptitude to fatten, but are very susceptible of cold from being almost entirely without hair. A cross of the Berkshire with the Suffolk and Norfolk pigs also is much approved in some parts of the country. A hardy kind is thus produced, which yields well when sent to the butcher; but even the advocates of this cross allow that, under most circumstances, the pure Berkshire is the best.

HAMPSHIRE.

Here there are two varieties, the one larger than the other; in colour they are either white or black and white with long necks and bodies,

flat sides, and large bones. The smaller variety are more easily fattened to a considerable size and weight, and make excellent bacon, but the larger kind require an extra amount of food to bring them to perfection, although when this object is attained they will often weigh from 600 to 800 lbs.

Considerable improvement has however been latterly effected by crosses of the Berkshire, Chinese, Essex, and Suffolk pigs, with the large old Hampshire hog. The animals resulting from these intermixtures are better shaped and more profitable; in fact, they bear about them the characteristics of the breed from which they were obtained. There is also a third variety of swine found in Hampshire, called the "Forest pigs," differing materially from the true Hampshire breeds, and in many points strongly resembling the wild boar, from which it is not improbable they derived their descent, for the last wild boars known to be at liberty in England were those turned into the New Forest by Charles I., and which he obtained from Germany with the view to the re-introduction of the fine old sport of boar-hunting. The Forest pig is broad shouldered and high crested; light and lean in the hinder quarters; has a bristly mane and erect ears; is of a dark or blackish colour; and lives chiefly on beechmast and acorns. This breed is no favourite in Hampshire; the animals are wild, fierce, not apt to fatten, and, from their peculiar make, do not cut up to advantage when killed; it is however now losing its distinctive characteristics, and becoming, as it were, more civilized or domesticated. Gilpin gives a very striking account of the sudden appearance of a herd of these semi-wild creatures.

"We well remember an occasion when we had thrown ourselves down at the foot of a great beech-tree, whence we looked abroad, from underneath its wide canopy of foliage, on a small track of sunshine, which, penetrating an opening in the wood, and falling athwart the ground beyond, gave a broader and deeper effect to the surrounding shadows. There was not a breath of air, and not a sound was audible; calmly we lay in all that listlessness of a dreamy musing which, to an idle mind, might seem like idleness, but which the philosopher, student, or moralist knows better how to appreciate.

"Suddenly a sound like that of warlike music mellowed by distance came upon our ears. We started so far up from our recumbent position as to lean upon one arm and listen intently, and not without some degree of awe, being almost persuaded that some wonderful fairy pageant was about to gratify our sight.

"The sound increased and grew harsher as it advanced, and as it drew yet nearer the tramp of what might easily have been imagined to be elfin chivalry accompanied it. At length, while we yet listened in mute expectation, the leading boar of a large herd of forest pigs came grunting into view, followed by all the musical members of his harmonious detachment.

"Whether it was the cheering invigorating effects of the sunshine, and whether there was something particularly savoury in the herbage of that spot, we know not, but the grunting swelled into a loud chorus; their snouts became more and more busy; their ears and tails kept up one continuous and joyous motion; and their small eyes seemed to flash back the sun's rays with unwonted eagerness of expression. It was

really an interesting sight; and were it not that swine were the subject of it, we should, and truly, say it was as beautiful as interesting. The creatures were in fine condition; their bristles glittered like silver; their bodies were as clean as if they were as regularly washed and combed as a lady's lapdog; and they seemed so full of freedom and happiness, that while looking on them we felt all the romance of forest life and recollections of the "merrie green wood."

"Wishing to observe and admire them more closely, we sprang up, but in so doing alarmed them, and off they galloped belter skelter, *saute qui peut*, with a speed that none of the porcine race not 'forest born' and bred could equal; and long after every one was out of sight, vanished in the mazes of the woodland, we still heard their retreating trumpets gradually dying away until lost in the distance."*

SUSSEX.

The breed of this country are by some authors supposed to have descended from the large spotted Berkshire swine; while others assert them to be a variety of the black-and-white Essex pig, if not the original stock. They are of moderate size, handsomely formed, thin-skinned, and black and white; not, however, spotted, but white at one extremity and black at the other. The hair is fine and long, but spare; the head long and tapering; the ears well set on and pointing forwards; the eyes quick and vivacious; and the snout fine. The chief fault in their make is, that the bones are somewhat too large. They grow quickly, feed well, fatten kindly, and will when full-sized weigh from 18 to 25 stone of 14 lbs.

Some of the finest pigs of this kind ever reared were in the possession of the Western family, at Felix Hall, Essex.

In speaking of the breeds of pigs belonging to this county we must not omit the now extinct Rudgwick swine, which derived their name from a village in Sussex, and were some of the largest hogs produced in England. They fattened but slowly, and were consequently deemed unprofitable, but yielded excellent meat and in considerable quantities. They have, however, passed away before the alterations produced by the general aim of the present system of breeding.

THE CHINESE SWINE.

Although these have been already noticed when speaking of Asia, we cannot now pass them over, as they actually form one of the recognised stock breeds of England. There are two distinct varieties, the *white* and the *black*; both fatten readily, but from their diminutive size attain no great weight. They are small in limb, round in body, short in the head, wide in the cheek, and high in the chine; covered with very fine bristles growing from an exceedingly thin skin; and not peculiarly symmetrical, for, when fat, the head is so buried in the neck that little more than the tip of the snout is visible. The pure Chinese hog is too delicate and susceptible of cold ever to become a really profitable animal in this country; it is difficult to rear, and the sows are not good nurses; but one or two judicious crosses have in a manner naturalized it.

This breed will fatten readily, and on a comparatively small quantity

* Gilpin's Forest Scenery.

of food; and the flesh is exceedingly delicate, but does not make good bacon, and is often too fat and oily to be generally esteemed as pork. They are chiefly kept by those who rear sucking-pigs for the market, as they make excellent roasters at three weeks or a month old. Some authors point out five, some seven varieties of the Chinese breed, but these are doubtless the results of different crosses with our native kinds; among these are black, white, black and white, spotted, and blue and white, or sandy. Many valuable crosses have been made with these

CHINESE FIG.

From a Sow sent direct from China to William Ogilvy, Esq., Hon. Sec. Zool. Soc.

animals; for the prevalent fault of the old English breeds having been coarseness of flesh, unwieldiness of form, and want of aptitude to fatten, an admixture of the Chinese breed has materially corrected these defects. Most of our smaller breeds are more or less indebted to the Asiatic swine for their present compactness of form, the readiness with which they fatten on a small quantity of food, and their early maturity; but these advantages are not considered by some persons as sufficiently great to compensate for the diminution in size, the increased delicacy of the animals, and the decrease of number in the litters. The best cross is between the Berkshire and the Chinese.

IRELAND.

Here the hog is, in the fullest sense of the word, a *domesticated* animal. The Irish pig is born in the warmest nook of his master's cabin, reared among the children, and often far better fed and more carefully

tended than the ragged urchins who play around him, for the peasant will half starve himself and children in order to have more food for his pig; and while the former have only potatoes, and few enough of them, the porker frequently gets not only a good meal of potatoes, but some porridge, or bran, or refuse vegetables in addition. He is in fact the chief person in the household; on him the poor man reckons for the payment of his rent or the purchase of the necessaries of life. Swine abound in all parts of Ireland; scarcely a peasant's cot hut numbers a pig among the family; and the roads, lanes, and fields in the neighbourhood of every village, and the suburbs of every large town, are infested with a grunting multitude.

Until lately, however, notwithstanding the value set on these animals, the real Irish pig was a huge, gaunt, long-legged, slab-sided, roach-backed, coarse-boned, grisly brute; with large flapping ears which almost wholly shrouded the face; of a dirty white, or black and white colour; with harsh coarse hair, and bristles that almost stood erect. It was also far from being a profitable animal, requiring a very considerable quantity of food, and when fat producing only coarse-grained meat. But since the facility of export has become greater, considerable improvement has been effected by the introduction of Berkshire and Chinese boars and sows, and crossing the old breed pretty extensively with these. Thus the unwieldiness of size and coarseness of bone have been diminished, and greater aptitude for fattening communicated, which latter qualification is invaluable to the poor peasant. There is, however, great room for still farther improvement, and we trust that before long some enterprising individuals will devote their energies to the task, and thus become the means of bestowing a great benefit on the peasantry of the "sister-isle."

Steam navigation has wonderfully increased the trade in pigs between England and Ireland, for we find that in 1821 only 104,501 of these animals were brought into Liverpool; while in 1837, 595,422 were imported. The cost of conveyance has been so materially decreased by the facility of steam-boat and railway conveyance, that this is not at all to be wondered at.

Irish pork or bacon is not so fine-grained or so finely flavoured as the English; and although imported in considerable quantities, sells for a much lower price than our own. This has been attributed by some to the pigs being entirely fattened on potatoes, but it is also referable to the innate coarseness of the animals themselves.

CHAPTER VII.

The Skeleton of the Hog—Skull and Snout—Teeth—Brain—Apoplexy—Inflammation of the Brain—Phrenitis—The Spinal Cord—Epilepsy—Palsy and Paralysis—Tetanus—Rabies—Nasal Catarrh—The Larynx—The Pharynx—The Os Hyoides—Strangles and Quinay—The Chest—Diseased valves of the Heart—The Bronchial Tubes—Inflammation of the Lungs or Raging of the Lights—Pleuro-Pneumonia—Epidemics.

A VERY slight acquaintance with that complicated and beautiful structure which we term the animal economy, will be sufficient to convince us that any rational method of investigating or treating disease

must be founded upon an acquaintance with the general construction of the frame, the derangements and alterations to which it is liable, and a concise notion of the various systems or sets of organs of which the body is composed. Without this amount of knowledge it will be impossible correctly to interpret those signs of alteration of structure or function which constitute the symptoms of disease, and indicate its nature and seat.

If we would understand how to regulate the working of some complicated machine, we must not content ourselves with a mere cursory glance at its exterior, but closely inspect the different parts; make ourselves acquainted with their shape, situation, and arrangement; inquire into the principles upon which the whole is constructed,—its mode of action, and the offices which each part was destined to perform. Proceeding thus, we shall arrive at a knowledge of the best means of preserving it from injury, repairing any accident that may happen to it, and maintaining it in a fit state for the efficient discharge of the duties it was intended to perform.

The animal economy consists of parts or organs, differing from each other in structure and function, yet all so intimately connected together, and so mutually dependent upon each other, that the co-operation of the whole is necessary to a state of perfect health; and if any one part suffer injury the neighbouring organs sympathize with it to a greater or less extent, and the working of the whole system is impaired. In order to arrive at a proper understanding of the functions of any one part of the body, we must study the whole; there is no other way of obtaining that insight into disease which will furnish us with a clear idea of the precise nature and seat of a malady, and the course of treatment most likely to be attended with success. The uninformed empiric who deals about his nostrums at random, is far more liable to put an end to the life of his patient than to arrest the progress of the disorder. Such men should never be allowed to tamper with the meanest animal. It is only to those who, from close study and long practice, have acquired an accurate knowledge of the anatomy, diseases, habits, and general management of domesticated animals, that their medical treatment can with safety be entrusted.

It is, however, by no means our intention in this work to give a formal treatise on the anatomy, physiology, and diseases of the pig, but simply to lay before our readers a tolerably comprehensive sketch of the general structure of the animal, and the alterations and evils to which certain parts are liable, and this divested as much as possible of all the technicalities of professional language. A description of the different parts, their form, situation, action, and functions, as well as their admirable adaptation to the ends for which they were designed, will lead us to a consideration of the diseases incidental to them—to the treatment proper to be adopted—and to some account of the various operations which it may occasionally be requisite to perform. In short, we would present them with a practical digest of all that is yet known relative to this too much neglected branch of veterinary science; one that shall serve as a book of reference in cases of doubt or emergency, and aid in introducing those great truths and leading doctrines, which form the groundwork upon which the practice of every branch of me-

dical science ought to be based, into the last strongholds of ignorance and empiricism.

In entering upon the anatomy and diseases of swine we may be said to take possession of a new and almost untrodden field, one as yet scarcely recognised as belonging to any earlier occupants; and here, in the onset, it will be as well to observe that, careful and lucid as we shall endeavour to make our descriptions, we should only mislead the agriculturist or grazier if we were to encourage him to believe that they will enable him wholly to dispense with a veterinary surgeon. Far from it; we would rather persuade him to seek at once the assistance of the well-educated and scientific practitioner, who, from close study, practical experience, and surgical skill, is qualified successfully to grapple with the most obscure and fatal diseases. We would enable him to assist the veterinary surgeon in his often arduous task, by giving him that information as to the previous symptoms, habits, &c., of the patient, which can alone enable him to proceed with certainty, and will tend to save the life of many a valuable animal; and, lastly, we would warn him against empirics.

Swine, from having been, until very lately, considered as a subordinate species of stock, have not yet, to any extent, become sharers in the benefits which an improved system of agriculture, and the present advancing state of veterinary science, has conferred upon other domesticated animals. When any thing goes wrong in the piggery the farmer too often, instead of exercising that shrewd sense which he turns to so good an account in almost every other instance, either sends for the butcher, or consigns the sick tenants of the sty to the care of an ignorant "pig-doctor," whose whole pretensions to leech-craft rest on the possession of some antiquated recipe, which he uses indiscriminately as a grand panacea for "all the ills swine's flesh is heir to," or on the traditionary lore he inherits from some ancestor famous in his day for certain real or supposed wondrous cures. The treatment adopted in such a case is usually of a very summary nature: a drench is administered, the principal ingredients of which consist in whatever abominations happen to come to hand first when this learned practitioner is summoned. The unlucky patient's tail is next cut off, or he is bled "between the claws," and the "doctor," after some learned clinical remarks to the bystanders, swallows the customary mug of beer, and leaves his patient to contend with his disease and the remedy, one or the other of which in most cases speedily brings the matter to a conclusion, unless, with all the obstinacy inherent in a pig's nature, he lives on in spite of both. The following anecdote, which appeared in one of the daily papers, is strikingly illustrative of the rough practice of the "village pig-doctor:"—

"A poor weaver laid the following complaint before the magistrate. He kept a pig, which, appearing to be unwell, he asked a pig-doctor to come and see it. The man came, examined the animal, stated that it had got 'a bit of a cold,' but he could soon give it a drink that should cure it. The price of this drink was to be 1s. 2d., and the poor man, agreeing to pay for it, the pig-doctor gave the animal some warm water, and promised to bring the pig-medicine in the evening. So beneficial were the effects of the water, that the pig was shortly running about as brisk as ever he was in his life. The drink was sent in the evening in

a broken-necked bottle, which was violently forced into the animal's mouth, in spite of the remonstrances of the owner. In the struggle the bottle was still more broken, and the pig's mouth bled very much. The poor man, however, paid the 1s. 2d., but on the following morning on going into the pig-sty found his pig lying dead. On its being opened three pieces of the glass bottle were found sticking in the windpipe."

Many similar instances of barbarity as well as gross ignorance might be added, but a narration of them would be of no practical benefit, and therefore we proceed at once to our legitimate subject.

SKELETON OF THE PIG.

THE HEAD.

- | | |
|---|--|
| A. Maxilla inferior, vel posterior—lower jaw. | D. Maxilla superior, vel anterior—upper jaw. |
| B. Dentes—the teeth. | E. Os frontis—the frontal bone. |
| C. Ossa nasi—the nasal bones. | F. Orbiculus—the orbit or socket of the eye. |
| | G. Os occipitis—the occipital bone. |

THE TRUNK.

- | | |
|---|---|
| H. Atlas—the first vertebra of the neck. | J. Vertebrae dorsi, vel dorsales—the vertebrae of the back. |
| I. Vertebrae colli, vel cervicales—the vertebrae of the neck. | K. Vertebrae lumborum, vel lumbales—the vertebrae of the loins. |
| | L. Ossa coccygis—the bones of the tail. |

FORE EXTREMITY.

- | | |
|-------------------------------------|---|
| a. Scapula—the shoulder blade. | f. Os naviculare—the navicular bone. |
| b. Humerus—the round shoulder bone. | g. g. Phalanges, vel ossa pedis—the first and second bones of the foot. |
| c. Sternum—the breast bone. | h. Phalanges, vel ossa pedis—the bones of the hoof. |
| d. Ulna—the elbow. | |
| e. Radius—the bone of the fore-arm. | |

HIND EXTREMITIES.

- | | |
|---|---|
| i. i. Pelvis (osaa innominata)—the haunch bones. | n. n. Os naviculare—the navicular bone. |
| j. j. Os femoris—the thigh-bone. | o. o. Digiti, vel phalanges (osaa pedis)—the first digits of the foot. |
| k. k. Patella—the stifle-bone. | p. p. Digiti, vel phalanges (osaa pedis)—the second digits of the foot. |
| l. l. Tibia—the upper bone of the leg. | |
| m. m. Tarsus, (one of which is the (N) os calcis)—the hock bones. | |

THE SKULL AND SNOOT.

As the skull of the hog differs in many respects from that of the horse, ox, sheep, or dog, we shall now proceed to notice those points of difference.

From the point of the occiput to the tip of the nasal bone the profile presents an almost unbroken sloping line. The position of the orbit of the eye is lateral, giving to the animal a side, rather than a forward range of vision. The space occupied by the orbital processes of the frontal bone in the ox and horse, is in the hog supplied by a cartilage. The frontal bones unite together early, and the parietals appear to form but one piece. The frontal sinuses proceed to the occiput, and are only separated from each other by some longitudinal or somewhat oblique bony layers which do not entirely intercept communication; these and the sphenoidal sinuses render the cerebral cavity narrow, in fact the size of it is only half that of the cranium viewed from the exterior. The ethmoid and turbinated bones are larger and more fully developed in the hog than in the ox or sheep, in fact they occupy an intermediate grade between those of the horse and dog, being larger than those of the former, and smaller than those of the latter; they are spiral, complicated, cellular, and offer an extensive surface for the expansion of the olfactory nerve; the ethmoidal fossa is very much sunk, of moderate size, divided by a very salient crest, and riddled with numerous holes.

The nasal bones of the hog are situated low down in the face, flattened, and well adapted to the situation and wants of the animal. They are attached to the frontals in a slightly curved direction across the face, by a strong denticulated suture. All communication between them and the lachrymal bones is cut off by the interposition of a projection of the frontals on either side; the suture between them and the superior maxillary is mortised; the anterior maxillary sends up a broad deep process more than half the length of the nasal bones, and the suture here is exceedingly strong. The bony nasal opening is but small, not one-sixth of the size of that of the sheep, and the apices of the bone form one sharp but rapidly widening point, which is carried forward to the anterior extremity of the maxillary. The suture between the nasals themselves is often so intricate, that before the animal is two years old the upper part of it is perfectly obliterated, and the nasal cavity appears as if only covered by one bone. A very slight comparison of the face of this animal with that of any other will prove that strength is the object here in view; strength towards the inferior part of the bone. In point of fact the snout of the hog is his spade, with which, in his natural state, he digs and grubs in the ground for roots, earth-nuts, worms, &c. And to render his implement more perfect an extra bone is added to the nasal bone. This one is short and trifling.

cial and placed directly before the nasal bones, with which, and with the edges of the anterior maxillary, it is connected by strong ligaments, cartilages, and muscles. This bone has been termed the *spade-bone*, snout-bone, and by some writers the *vomer*, from its supposed resemblance to a ploughshare. By it and its cartilaginous attachments is the snout rendered strong as well as flexible, and far more efficient than it could otherwise be; and the hog often contrives to give both farmers and gardeners very unpleasant proofs of its efficiency, by ploughing up deep furrows in newly sown fields, and grubbing up the soil in all directions in search of his living and dead food.

The palatine bones constitute the crescentic and posterior border of the palate and nasal cavity; they do not advance further than just before the last molar tooth, instead of occupying a considerable portion of the palate. The palatine processes consist merely of bony laminæ.

As roots and fruits buried in the earth form the natural food of the hog, his face terminates in a strong muscular snout, insensible at the extremity, and perfectly adapted for turning up the soil. There is a large plexus of nerves proceeding down each side of the nose, and ramifying over the nostril, and in these doubtless reside that peculiar power which enables the hog to detect his food though buried some inches below the surface of the ground. The olfactory nerve too is large, and occupies a middle rank between that of the herbivorous and carnivorous animals; it is comparatively larger than that of the ox: indeed few animals, with the exception of the dog, are gifted with a more acute sense of smell than the hog. We have already spoken of the sow which was taught to hunt partridges, and proved as sure a finder and as staunch a backer as any pointer ever bred. To the acute sense of the hog are epicures indebted for the truffles which form such a delicious sauce, for they are the actual finders. A pig is turned into a field and suffered to pursue his own course and watched. He stops and begins to grub up the earth, the man hurries up, drives him away, and secures the truffle, which is invariably growing under that spot, and the poor pig goes off to sniff out another, and another, only now and then being allowed by way of encouragement to reap the fruits of his research. And how many a school-boy has by watching a hog along the hedge sides, and driving him away just as he began to dig, secured a fine juicy earth-nut.

The muscles, too, of the snout of the hog require some notice. According to Cuvier there are four principal muscles proceeding to it; the superior of these proceeds from the lachrymal bone, which occupies a rather large rhomboidal space upon the cheek, and its tendon bears upon the snout, but does not approach sufficiently near to it to unite with it. The next two are situated immediately beneath, and proceed from the maxillary bone; these are partially united, but their tendons pass on separately, one on the one side, and one on the other of the extremity of the snout; and the fourth and smallest passes obliquely beneath the tendons of the others, from the nasal bone towards the insertion of the second and third muscles. These longitudinal muscles are enveloped in annular fibres, which appear to be a continuation of the *orbicularis* of the lips, and give to the snout its extreme flexibility.

THE TEETH.

The hog has fourteen *molar* teeth in each jaw; six *incisors* and two *canines*; these latter are curved upwards, and commonly denominated *tushes*. The molar teeth are all slightly different in structure, and increase in size from first to last; they bear no slight resemblance to those of the human being. The incisors are so fantastic in form as to baffle description, and their destined functions are by no means clear. Those in the lower jaw are long, round, and nearly straight; of those in the upper jaw four closely resemble the corresponding teeth in the horse, while the two corner incisors bear something of the *fleur de lis* shape of those of the dog. These latter are placed so near to the tushes as often to obstruct their growth, and it is sometimes necessary to draw them, in order to relieve the animal, and enable him to feed.

It is seldom that it becomes necessary to ascertain the age of the hog by inspecting his teeth, nor is it by any means an easy task to do so, but still it may occasionally be interesting, and, with reference to those intended for breeding, important to be able to do so when necessary.

The calculation of the age of the hog by means of reference to the mouth has not yet been carried beyond three years; no writer seems to have gone much beyond the protrusion of the adult middle teeth of the lower jaw.

The hog is born with two molars on each side of the jaw; by the time he is three or four months old he is provided with his incisive milk teeth and the tushes; the supernumerary molars protrude between the fifth and seventh month, as does the first back molar; the second back molar is cut at the age of about ten months, and the third generally not until the animal is three years old. The upper corner teeth are shed at about six or eight months, and the lower ones at about seven, nine, or ten months old, and replaced by the permanent ones. The milk tushes are also shed and replaced between six and ten months old. The age of twenty months, and from that to two years, is denoted by the shedding and replacement of the middle incisors, or *pincers*, in both jaws, and the formation of a black circle at the base of each of the tushes. At about two years and a half or three years of age the adult middle teeth in both jaws protrude, and the pincers are becoming black and rounded at the ends.

After three years the age may be computed by the growth of the tushes; at about four years, or rather before, the upper tushes begin to raise the lip; at five they protrude through the lips; at six years of age the tushes of the lower jaw begin to show themselves out of the mouth, and assume a spiral form. These acquire a prodigious length in old animals, and particularly in uncastrated boars; and as they increase in size they become curved backwards and outwards, and at length are so crooked as to interfere with the motion of the jaws to such a degree that it is necessary to cut off these projecting teeth, which is done with the file or with nippers.*

* *Traité de l'Age du Cheval, du Bœuf, du Mouton, du Chien, et du Cochon, par N. F. et J. Girard.*

THE BRAIN.

This important organ is not so large as from an external view of the cranium we should be led to suppose, the frontal and sphenoidal sinuses contracting the limits of the cranial cavity and rendering it narrow; it is, however, considerably larger in proportion to the size of the animal than that of the ox or sheep, being about 1-500th part of the weight of the animal, while that of the ox is only 1-800th part, and that of the sheep only 1-750th part. The irregularities of the surface, or those prominences and depressions which define the organs in phrenology, are more marked in the pig than in the horse, taking the size of the animal into consideration, but not so much marked as in the dog.

The brain of the hog, like that of our other domesticated animals, is composed of two substances differing materially in appearance and structure; the one is of a pale gray or ashy hue, and termed the *cortical* or *cineritious substance*, and the other, from its pulpy nature and from being found deeper in the brain, the *medullary substance*.

These two distinct component parts of the brain are allowed by all scientific men to be intended for the discharge of two distinct functions. The mind or reasoning power is supposed to reside in the cineritious portion; and hence the preponderance of that substance in the human brain; while the medullary portion is merely the recipient of outward impressions upon the senses. There is very little difference between the proportions of these two substances in the brain of the hog and that of the sheep; if any thing, the hog has more of the cineritious portion than the ox; a proof, physiologists would say, that his reasoning powers or moral faculties are greater. We have already endeavoured, we know not how successfully, to vindicate him from the charge of utter stupidity and unteachableness so generally brought against him, and pleaded the slight intercourse, compared with that enjoyed by other animals, which he has with man as the cause of it. A philanthropist once declared his intention of "bringing up a pig in such a way as should tend to develope his whole nature, and give him a fair chance of acting out his character, and showing what a pig was capable of being." We may smile at such an Utopian idea, but are we by any means certain that under different treatment swine might not become intelligent and capable of attachment? There are anecdotes enough to prove them possessed of memory, attachment, and social qualities; but at present the system of treatment affords no scope for the development of any but mere brute and gluttonous instincts.

APOPLEXY.

As this is a disease which is chiefly induced by plethora, laziness, want of exercise, high feeding, and such like causes, it is not to be wondered at that it is frequent among swine; and in by far the majority of cases it is fatal; for either the animal dies suddenly without any precursory symptoms, or the progress of the attack is so rapid that before help can be obtained or remedies administered all is over. Where, however, the apoplexy does not destroy its victim in a short space of time, it may be subdued and the animal temporarily cured; but only for awhile; it invariably dies soon afterwards of inflammation of the

brain. Sometimes apoplexy will run, like an epidemic, through a whole piggery, and where this is the case the causes of it must be diligently sought out and carefully removed.

The precursory symptoms which prognosticate apoplexy are dullness, disinclination to move, heaviness of the head, an uncertain and staggering gait, wildness and inflammation of the eyes, with apparent loss of sight, no appetite, and general numbness. The treatment must be prompt and energetic: bleeding from the palate; Epsom salts and sulphur as purgatives; or emetic tartar dissolved in water to induce vomiting. Strict attention to diet will be requisite for some time afterwards. No stimulating food should be given; the water should be slightly nitrated, and the animal bled at least every three months.

INFLAMMATION OF THE BRAIN.

Inflammation both of the substance and of the membranes of the brain is by no means of unfrequent occurrence, and almost invariably follows an attack of apoplexy. It is also induced by heating or exciting or indigestible food, as an over-feed of grains, of new corn, &c. The precursory symptoms are dullness, redness of the eyes, and disinclination to move; but as the inflammation becomes more intense the animal runs wildly to and fro, seems blind and unconscious where he is going, runs against every thing; the pulse is small and rapid; and the breathing slightly accelerated. The first thing to be done is to bleed, from the palate if possible; if not, or if sufficient blood cannot be obtained from there, let incisions be made in the ears, and these repeatedly washed with warm water, as such a proceeding materially increases the bleeding. *Magn. sulph.* with ginger should be given internally as a purgative. Enemas (clysters) have also a beneficial effect, and then the animal should have repeated cooling doses of sulphur. Castor oil and jalap have been given as purgatives; and the system stimulated by the application of a blister to the throat.

PHRENITIS.

This is a disease very much resembling the last mentioned, and is often called brain-fever or frenzy; it arises pretty much from the same cause; all excitants of the system, all things which tend to drive the blood to the head, will induce it. The symptoms are prostration of strength, blindness, frenzy, and often convulsions. The treatment must consist in copious bleedings and strong purgatives, which should be followed up by doses of sulphur to keep the bowels open. Croton oil with tincture of ginger has been given in extreme cases, and with beneficial effects. The dose for a moderate sized animal is about two minims of croton oil and one dram of tincture of ginger.

SPINAL CORD.

Next to the diseases of the brain follows a consideration of those arising from the spinal cord. This proceeds from the brain to the tail, and is divided by a central line on the upper and under surface throughout its whole extent, forming it into two separate columns, each of which has been proved to possess a distinct and separate function, the

inferior surfaces being connected with voluntary motion, and the central ones on the upper surface with sensation.

EPILEPSY.

The pig occasionally exhibits all the symptoms of epilepsy in their most frightful intensity, and whoever has carefully marked the habits of swine when not confined to the sty will easily be able to account for this; for, obtuse and stupid as it is the custom to denominate them, there is more excitability and nervousness in these animals than in many that have the credit of being more delicately organized. Note the manner in which they are affected by the approach of wind or storms—how they run about in a state of highly nervous excitement with straw in their mouths; note the sympathy and terror a whole herd will exhibit while one of them is undergoing the operation of spaying or ringing, how they squeak in concert with his cries; see them at a fair under the irritation of strange scenes and noises, and we shall find sufficient indications of a susceptibility of impression to account for swine being peculiarly subject to epilepsy.

The prognostics are constant grunting, restlessness, acceleration of breathing, pallor of the skin, and a staggering gait. Then the animal suddenly falls as if struck by lightning, and for a few moments lies perfectly motionless; after which convulsions come on gradually, increasing in intensity until they are fearful to behold; the countenance is distorted; the neck curved in every direction; and the legs alternately drawn up to the body, and extended with momentarily increasing rapidity. The eyes protrude, the pupils are distended, and the balls roll about. The tongue is protruded and fixed between the clenched jaws; the teeth grind together, foam and saliva flow from the mouth. The pulse is wiry and small at first, then hard and bounding, and, as the intensity of the fit decreases, irregular and intermittent. Throughout the whole of the fit the animal remains perfectly unconscious, and as he recovers gets up, tries to hide himself in the litter or in a corner of the sty, and looks terrified and wild; then gradually the impression passes away, and he creeps out and begins to eat again. The seizure of one pig is often but a prelude to that of the greater number of those contained in the sty. The fits often succeed each other rapidly, two or three occurring in one day; and the cries uttered by the animals while in them are distressing in the extreme.

Medical treatment can only be resorted to in the intervals between the fits, and is seldom successful. It consists of cold effusions applied to the head, bleeding, and energetic purgatives, followed up by low diet, perfect quiet, and cooling medicines. The best way of keeping the head cool is to tie a piece of cloth about it, and then keep this constantly wet. A very efficient cold lotion for this purpose may be composed of a pint of vinegar to two quarts of water, and one ounce of *sal ammoniac*. Salts and calomel may be given as purgatives.

It is often difficult to determine what are the precise causes of epilepsy; the immediate one is generally some excitant or stimulant acting on a system predisposed by cerebral inflammation, or by intestinal irritation arising from worms, or other sources, to take on disease.

We quote a case communicated by Mr. Cartwright, of Whitechurch,

to whom we are indebted for much useful information relative to the diseases of swine :—

“In 1825, I saw a pig that was taken ill in the following manner :— He was a little stupid and dull, and now wandered about the sty unconsciously for a few minutes, and then appeared to be quite well ; but in a few days after he became worse : he would move forwards until he came to one wall, and then retreat backwards until he came to the other wall ; and made a grunting and squealing noise all the time the fit was on him, which was usually a few minutes, and sometimes longer ; and he had them every quarter of an hour, and even oftener. His fits continued to increase ; when he had been thus for about five days he began, after so backing himself, to fall down at full length, stretch out his legs and tumble about, and appear as if dying, and make a shrieking noise as if in great pain, and seem to be blind. His pulse was very quick and full during the fits, but subsided a great deal when they were over. He ate at intervals between the fits when food was put to him. He continued in this latter bad state for three or four days, and got well in a few days after. I gave him salts and calomel during his illness, bled him in the tail and ears and between his claws ; but little blood, I fancy, was obtained from all the places ; and I kept his head wet with cold water.

“About the same time a miller in this neighbourhood lost five or six in a similar way, but I had not an opportunity of opening any of them.”*

PALSY OR PARALYSIS.

This is by no means a disease of frequent occurrence in our own country. It is treated of by French writers, who attribute it to low marshy situations, bad or damaged food, or the avarice of the pig-owner, who, in order to fatten the animals more rapidly, gives them highly stimulating food, which irritates the intestinal canal, and through it the spinal cord. Eric Viborg, an authority quoted by Hurtrel D'Arboval, recommends wholesome food, clean straw, a dose of common salt as a purgative, and drenches of common salt and gentian.†

But there is a kind of partial palsy which is caused by the presence of *cysticercus cellulosa*, a hydatid peculiar to the pig. M. Dupuy gives the following case which came under his observation :—

“Palsy of the hind limbs, with loss both of motion and feeling, was observed in a pig eighteen months old. On carefully examining him after death, the muscles were discoloured and softened. There were in the psoas muscles numerous cysts enclosing hydatids. Other cysts with their parietes more thickened and fibrous inhabited the muscles surrounding the trochanter, containing likewise hydatids. These parasites are also found in the lungs, the liver, and the cortical substance of the kidneys.

“Between the internal surface of the cyst and the hydatid was a fine white powder, resembling pulverized bones. The spinal marrow was softened about the lumbar and sacral regions, and the membranes were slightly reddened, particularly about the roots of the lumbar nerves.”‡

* Veterinarian.

† Hurtrel D'Arboval, Dictionnaire de Médecine Vétérinaire.

‡ Journal Théorétique et Pratique.

It is generally the hinder parts of the pig which are paralyzed, either wholly or partially; in the former case the animal is totally unable to rise, in the latter he totters in his gait and falls when attempting to walk. Paralysis frequently accompanies chronic disease of the digestive organs, and is attended with loss of appetite, acceleration of the pulse, and swelling of the tongue. This disease is seldom obstinate; a removal of the predisposing cause, good nourishing food, a clean and well-ventilated sty, moderate exercise, and gentle purgative or cooling medicine, will generally restore the animal to perfect health in a short space of time.

TETANUS.

This disease, which is commonly denominated *Locked-jaw*, is by no means an unfrequent malady among pigs. The symptoms are at first spasmodic motion of the head and of one or more of the extremities, grinding the teeth and rigidity of the jaws. This is soon followed by stiffness of the neck and greater part of the frame, and an unnatural up-raised position of the head. The castration of young pigs will frequently produce this disease, especially if the animal is too well fed for a few days after the operation. It also often appears among pigs that are driven far to market, especially if when heated by travelling or exposure to the sun, they are suffered to roll themselves in ditches or streams, as they will endeavour to do. Bleeding, warm baths, lotions, &c., friction with stimulating oils, purgatives if they can be got into the mouth, if not enemata and anodynes, are the most efficient remedies. But the disease is too often fatal, and runs its course very speedily; if the animal survives the first twelve or eighteen hours some hopes of his eventual recovery may be entertained.

RABIES.

Swine are by no means exempt from this frightful disease; there are numerous cases on record in which they have been inoculated by the bite of rabid dogs, and Hübner relates a case of inoculation from the bite of a rabid fox. The symptoms of rabies in the hog are peculiarly interesting at times from the resemblance many of them bear to those of the human being. At first there is dulness and indisposition, and the pig is continually licking the bitten part. Subsequently some are exceedingly ferocious, snapping at every body, gnawing every thing which comes in their way, dashing themselves against walls, or leaping over all obstacles. Others, again, are dull, stupid, refuse their food, stagger when they attempt to rise, and are paralyzed in the hinder parts. There is no absolute dread of water, but evident inability to drink. An animal that we saw went to the trough, smelt at the food, and brought his nose nearly into contact with it, then started back, trembled violently, and elevated his snout high in the air. Once or twice he attempted to take portions of meat and vegetable from the wash, but the attempt was always accompanied or followed by universal rigour and shuddering, during which the food was dropped from the mouth, evidently proving that the organs of deglutition were powerfully affected.

The animal is in a highly nervous state, and the sensibility of the skin is so excessive, that even if his mother licks him he screams with agony, and buries himself in the litter, uttering shrill squeaks on the approach of any one, or springs up into the air if he hears a loud noise,

and falls down again in convulsions. There is in general no great secretion of saliva in these animals, and the delirium which characterizes rabies in the dog is rarely seen, or when met with is less evident and distinctive.

As yet this disease has been but little studied in pigs. Mr. Pritchard, V. S. of Wolverhampton, gives the following interesting account of some cases he met with:—

“A rabid dog entered the farm-yard of Mr. George Strongitharm of Calderfield, near Walsall, on the 27th of December, 1835, and attacked some pigs, which making a considerable noise, aroused Mr. S. and his servants from their beds, and they proceeding with their guns already loaded, discovered him, and succeeded in destroying him. Two of the pigs had evidently received wounds in their noses from the dog, which soon got well, no curative or preventive measures being had recourse to, and without much irritation or swelling taking place. After a fortnight had elapsed, nothing outward being observable in them, they were again turned into the yard to their old companions.

“A day or two after, on the entrails of a sheep being thrown to the pigs, all came and partook of it except the two that had been bitten. One of these was found dead in the litter, with a quantity of froth and slaver about his mouth; the other, on coming out of his bed into the air, immediately jumped up on all four legs like the bound of a deer, a yard at least from the ground, and threw from his mouth a portion of thick slaver and froth. Upon being again placed in the sty he was much convulsed, and made a shrill squeaking noise, his mouth was filled with saliva, and held continually open nearly half an inch, except when champing his under jaw, which he frequently did with considerable twitching of the superficial muscles. He refused to eat or drink, gradually got worse, and died on the third day.

“Three weeks after another of the pigs was taken ill. The symptoms were much the same. The effect of water was tried, and upon being thrown upon him caused him considerable distress, so that he leaped into the air and dashed his head against the wall, appearing quite delirious. He died on the second day. Not long afterwards another pig was attacked, the symptoms being similar to those in the former cases, only more violent; he died twenty-four hours afterwards, nothing having been done to disturb him. None of the pigs ate or drank any thing after they were first taken ill.”*

And the case we are now about to quote was communicated by Mr. Heaton, a human surgeon:—

“About May, 1829, while visiting a patient, I was told that in a sty at the bottom of the yard there was a mad pig. Thither I repaired, when I was informed by its owner that the animal had been bitten about three weeks before by a strange dog, which had passed through the yard, and who was at the time, by those who saw it, declared to be mad; the dog appeared to be greatly alarmed and proceeded with swiftness; it was afterwards seen for the last time in some fields at the outskirts of the town. From the statement of the man it would appear that, on the morning of the day previous to that on which I saw the pig, the animal began to exhibit symptoms of great oppression at the

* The Veterinarian for 1836.

præcordia; to this succeeded gradually inability to stand, fearful cries, and general uneasiness when disturbed, foaming at the mouth, and a disposition to eat whatever came in the way, &c. At six o'clock in the afternoon of the second day I first saw it, covered with straw and apparently quiet, until the rattling of the sneck of its door seemed to awaken the most painful apprehension, and its mental agony seemed almost insufferable. The sense of sight seemed no less acute than that of hearing, which was manifested by the animal's convulsive efforts to hide even its head beneath the straw; this accomplished, it became somewhat tranquil, and was constantly devouring its own litter, excrement, &c., &c. Its eyes had the suspicious glance of those of a phrenitic patient, its breathing was preternaturally quick, and its efforts to stand wholly abortive. In this state it continued two hours, when half a pint of train oil was attempted to be poured into its mouth, the greater part being wasted, and the animal instantly expired. I regret that the approaching night, and the man's desire to bury the carcass, restricted the post-mortem examination, which merely went to show that upon the division of the costal cartilages the lungs protruded, as if too large for the cavity of the thorax, and, being cut into, poured forth a frothy mucus, resembling in colour and consistence soap lather; the stomach and duodenum were filled with the matters above described to have been eaten, not however impacted, probably owing to the premature death. I have little doubt from the symptoms that, had the examination gone so far, the vessels of the brain and spinal cord would have been found injected. The splash of water certainly caused disquietude; but, inasmuch as noise of any sort produced similar effects, it is doubtful whether aversion to fluids existed; and yet the circumstance of death instantly following the oil-draught, would warrant the belief that spasms of the muscles of deglutition, with the temporary closure of the glottis, occasioned suffocation and death."

Among all the numerous cases of rabies which we have met with in the course of our practice, we have never had the opportunity of examining the post-mortem appearances of a rabid pig; but it seems to be generally admitted by those who have done so that there is invariably inflammation about the glottis, and very considerable inflammation of the villous coat of the stomach, especially about the pylorus, towards the cardia, and on the surface of the two rugæ; in some parts the inflammation had almost merged in mortification. The stomach is generally filled with every kind of filth and rubbish, and the bladder distended with urine.

The disease generally appears in the third or fourth week after the animal has been inoculated, but it has been known to lie dormant for two months.

Incision of the part and the application of the cautery as soon as possible after the animal has been bitten, are the only preventive means: cure there is none when once the disease has made its appearance, and those who rely on the infallible nostrums of some learned "pig-doctor," will find themselves disappointed; the symptoms may be alleviated by certain drugs, but rabies is incurable.

We are not aware that rabies has ever been known to be communicated by the bite of a pig, but Julian Palmarius states that he has seen

horses, cattle, and sheep, become rabid from eating the straw in which rabid pigs had lain; and Dr. Shackmann corroborates the fact.*

It has been a much disputed point whether or not the flesh of animals which have died rabid can be eaten with safety. Two eminent scientific men in Paris ate of such flesh without experiencing any bad effects. The carcass of an ox that had been bitten by a rabid dog, and had exhibited all the symptoms of rabies, was cut up and sold, but it did not appear that any of those who ate of it experienced the slightest inconvenience. Again, at the Royal Veterinary School at Alford, the tongue of a rabid horse was given to a dog; the animal devoured it, and lived on in perfect health.

But the opposite party bring forward as many authenticated facts in support of the contrary opinion, and the one with which we now chiefly have to do is narrated by Schenkus: "A tavern-keeper, in the duchy of Wurtemberg, served up the flesh of a pig that had died rabid to some customers who were dining at his inn. All those who partook of it were shortly afterwards attacked with rabies." Pierre Borel records a very similar case.†

We should most strongly urge the prudence of abstaining from the flesh of all rabid animals, and not only of abstaining from it ourselves, but putting it out of the reach of other animals; and the best way to do this is to bury the carcass six or eight feet under ground, cover it carefully and closely up, and plant the spot with thorns.

NASAL CATARRH.

We have already spoken of the formation of the nose or snout of the pig, and will now proceed to describe a disease vulgarly called the *snuffles* or *sniffles*. It is characterized by defluxion from the nose in the first place, and its advance is so gradual as to be almost imperceptible. But it gains ground daily—attacks the respiratory passages—cough and sneezing come on—there is evident difficulty of swallowing, and the respiration is impeded by the mucus formed. After some time the membrane of the nose becomes thickened, the nostril swelled and deformed, and the snout drawn on one side. Blood is often discharged from the nostril, and when this has been the case all the symptoms are abated and the animal seems relieved for awhile. But it too frequently happens that this discharge or hemorrhage returns again and again, each time in increasing quantities, until the strength of the animal becomes so undermined that notwithstanding the utmost care and the most nourishing diet, he dies of exhaustion, or perhaps, as it may be more properly termed, consumption.

This disease, which strongly resembles glanders and distemper, is like them hereditary, and may be communicated from either the male or female parent. It also results from exposure to damp or cold.

Emetics and tonics are the best means of combating it. A solution of sulphate of copper in doses of from three to five grains morning and night will sometimes eventually effect a cure, assisted by strict attention to diet and regimen. But in by far the majority of cases the dis-

* Palm., de Morb., Contag., and Shackmann, on Hydrophobia.

† Delafond's Sanitary Police of all Domesticated Animals.

ease runs its course and terminates fatally, for it has generally gained the upper hand before much notice is taken of it.

THE LARYNX.

This instrument of voice consists of five cartilages united to one another by a ligamentous substance, by distinct articulations, and by a seemingly complicated but really simple muscular apparatus. In form it is an irregular oblong tube, exceedingly flexible, and capable of adapting itself to all the natural or morbid changes of the respiratory process, and to the production of all the various intonations of sound or voice by which the animal expresses his emotions. It is placed at the top of the windpipe, guards the exit from the lungs, and prevents the passage of food into the respiratory canals.

The *Ericoid cartilage* constitutes the base and support of this organ, and serves in great measure as a bond of union to the rest.

Placed above and resting upon this are the *Arytenoid cartilages*, prolongations of which rest upon the *Chordæ vocales*, and influence their action. The vocal ligaments take an oblique direction across the larynx in the pig instead of a straight one, so that the angle is at a considerable distance from the thyroid cartilage. They have also a curious slanting direction, the anterior angle being depressed and the arytenoid portion elevated. About the middle of the *chordæ vocales*, and immediately above them, are two *sacculi*, which are generally supposed to be concerned in the act of grunting. From the anterior parts of the larynx springs the *epiglottis*, a heart-shaped cartilage placed at the extremity of the opening into the windpipe, with its back opposed to the pharynx; its use is this: food passing from the pharynx in its way to the *æso-phagus* presses down the epiglottis, which, closing the aperture of the larynx, prevents any portion of the food from entering it. As soon as the food has passed, the elasticity of the epiglottis, assisted by that of the membrane at its base, and still more by the power of the *hyo-epiglottideus* muscle, enables that cartilage to rise up and resume its natural position.

The *thyroid cartilage* envelops and protects all the rest, and shields the lining membrane of the larynx, which vibrates under the impulse communicated by the passage of the air, and gives the tone or voice.

In the larynx of the hog we find that beautiful adaptation of means to the end. The space between the arytenoid cartilages is less, comparatively speaking, than in the horse or dog, speed not being required in swine. The epiglottis too is larger than in the ox, sheep, or horse, and differently constructed; it is more flexible, from the cellular ligamentous substance at the base of it being looser; and from its increased size, and the curved direction of its edges, it not only covers the opening into the windpipe, but in a manner embraces the arytenoid cartilages when pressed down by the passage of food, a formation admirably suited to an animal who is constantly plunging his nose and muzzle into mud or dirt, and who by blowing into his food in the peculiar way pigs are apt to do in order to stir up the sediment would otherwise be constantly getting some irritating and noxious matters into his windpipe. The inferior cornu of the thyroid bone is comparatively more developed in the hog than in other domesticated animals.

THE PHARYNX.

The pharynx, to which we just now alluded, is a membranous, muscular, funnel-shaped bag, extending from the root of the tongue to the larynx and œsophagus, wide in front and becoming gradually narrower until it terminates in the œsophagus. Its office is to convey the food from the mouth to the upper part of the gullet, and this it performs by means of its lining muscles. Properly speaking, we ought perhaps to have noticed it when speaking of the digestive system, but as we are proceeding from the head to the neck we have included it in this division of our subject.

THE OS HYOIDES.

This is a body which embraces the thyroid cartilage of the larynx, and give support and protection to it, and also affords attachments to the *hyo-glossus longus* muscle, or that which draws the tongue into the mouth; the *brevis*, which fulfils a similar office; the *hyo-pharyngeus*, which dilates the pharynx; the *anterior constrictor pharyngeus*, which contracts the pharynx, and several others.

This bone in the human being is supposed to resemble the Greek letter upsilon; in the horse it may be compared to a spur, but in the swine it is different. This animal requires a freer use of the tongue. The shorter cornua are stronger than in the horse, or even the ox and dog; the central one is less developed, and the longer cornua is thin and insignificant. There is also considerably less ligament interposed between this bone and the thyroid cartilage, which it almost closely embraces. We will now proceed to a consideration of the diseases of the throat and neck.

STRANGLES OR QUINSY.

These diseases are of very frequent occurrence, and, as they are rapid in their progress, generally exceedingly fatal. They chiefly attack fattening hogs.

The glands under the throat begin to swell, and thus affect not only the respiratory organs but the act of swallowing: impeded respiration, hoarseness, and debility then supervene; the pulse becomes quick and unequal, the head to a certain extent palsied, the neck swells, tumefies, and rapidly goes on to gangrene; the tongue hangs from the mouth, and is covered with slaver; and the animal gradually sinks. In the commencement of the disease very simple treatment, as cooling medicines, attention to diet, and care and warmth, will often suffice to check it; but when the swelling, impeded respiration, and difficulty of swallowing has come on, recourse must be had to more energetic treatment. Bleeding and purgatives are first indicated; setons and puncture of the swollen glands have also been recommended, and in extreme cases there is no reason why we should not have recourse to blisters and external stimulants as counter-irritants.

A diseased animal should never be allowed to remain among healthy ones, as this malady is so infectious that it may almost be regarded as an epizootic.

Mr. Cartwright, veterinary surgeon, of Whitchurch, who has paid much attention to the diseases of swine, gives the following account of some fatal cases of inflammation of the glands of the throat in the "Veterinarian:"—He says that he had six pigs attacked at nearly the same period. Their respiration was very quick; they husked and foamed at the mouth. They could not bear to be pressed on the throat, and swallowed liquids with difficulty. To some of them jalap was given, and to others castor and goose oil. One was blistered under the throat, and all bled by cutting off their tails. They died in the course of eight and forty hours from the commencement of the disease.

On examination he found much inflammation under the jaws and throat, and also much of swelling with effused serum. In some of their windpipes, and the branches of the bronchia, there was a great quantity of mucus, but no apparent inflammation. In one the heart appeared to be inflamed, but most probably sympathetically.

Columella thus speaks of these diseases:—"Such swine as have swellings of the glands under the throat must be let blood under the tongue; and when it has flowed abundantly, it will be proper that their whole mouth be rubbed over with bruised salt and wheat-meal. Some think it a more present and effectual remedy when they pour into each of them, through a horn, three cupfuls of *garum*, or salt-fish pickle; then they bind cloven tallies, or cuttings of fennel-giant with a flaxen cord, and hang them about the necks so that the swellings shall be touched with the fennel-giant cuttings.*

If we may judge by the writings of the ancients, the most prevalent diseases among pigs were those of the glands of the throat. Didymus gives a long and accurate description of them.

Hurtrel D'Arboval also gives an account of a disease of the glands of the throat, which he denominates *Poil piqué, maladie piquante*, or *soie*, and states it to be peculiar to swine: he thus describes it:—

It is situated on one or both sides of the neck, between the jugular vein and the tracheal artery. On the part affected is seen a raised tuft of hairs, differing from any of the others, being hard, rough, dull, and discoloured, and exceedingly painful to the touch; and if one be pulled out the skin comes away with it. At first there is only a slight depression or concavity of the part; but the skin soon becomes red, then violet-coloured, the hairs conglomerate, the parts become softened, tumefied, and even proceed to mortification. Meanwhile the animal betrays symptoms of thirst; there is dulness, loss of appetite, and grinding of the teeth. As the malady progresses the patient becomes inert, deaf, insensible to blows, lies down constantly, and totters and falls if compelled to rise; the flanks heave, the mouth is hot and full of slaver, the tongue red and inflamed, the lower jaw convulsed, and the conjunctiva injected; the animal utters plaintive moans, and if not speedily relieved dies of suffocation, from the effects of the pressure of the tumour upon the air-passages.

D'Arboval attributes this disease to the irritation caused in some of the cutical tissues by the abnormal growth of the tuft of hair, which uniting with some internal sympathetic irritation induced by heating food, damp litter, hot ill-ventilated sties, or such like prejudicial in-

* Columella's Husbandrie, book vi.

fluences, acts locally and determines this disease of the glands. Other French writers believe it to be epizootic and to arise from certain miasmatic influences.

Tonics, acidulated drinks, warmth, cleanliness, strict attention to diet, and the application of actual cautery to the root of the evil—the tuft of hair—is the treatment prescribed.*

THE CHEST OR THORAX.

In the human being this constitutes the superior, and in quadrupeds the anterior portion of the body; it is separated from the abdomen by the *diaphragm*. This latter is of a musculo-membranous nature, and is the main agent in respiration; in its quiescent state it presents its convex surface towards the thorax and its concavity towards the abdomen. The anterior convexity abuts upon the lungs, the posterior concavity is occupied by a portion of the abdominal viscera. The diaphragm of the pig resembles that of the ox and sheep.

The chest is divided into two cavities by a membrane termed the *mediastinum*, which evidently consists of a duplicature of the *pleura* or lining membrane of the thorax. The *pleura* is a serous membrane possessed of little or no sensibility, and acted upon by but few nerves. It is smooth and polished; covers the bony wall of the thorax from the spine to the sternum, and from the first rib to the diaphragm, and dilating and forming a kind of bag which spreads over and contains the whole of the lung.

The lungs form two distinct bodies, the right being somewhat larger than the left one; they are separated from each other by that folding over of the *pleura* termed the *mediastinum*, and hence may be said to be enclosed in separate bags, or to have distinct *pleuras*. Each lung is subdivided. The right one consists of three unequal lobes, the smallest of which is again subdivided into numerous lobules, differing in number in different swine. The left lung consists of two lobes, and the scissure between these is not very deep.

Beneath the left lung the heart is situated and partially enclosed in another membranous bag termed the *pericardium*, which closely invests, supports, and protects it. The heart has two sides, the one devoted to the circulation of the blood through the lungs, and the other to its circulation through the frame generally. Each side is divided into two compartments, the one above, the other below, which are termed the *auricles* and *ventricles*. The right auricle as well as ventricle is larger than the left and its parietes are thinner. The longitudinal tendinous cords of the ventricle are more firm and distinct in the pig than in the ox or sheep, and the fleshy prominences shorter. The tendinous cords of the left ventricle are few in number, large, and ill defined. The aorta of the pig separates almost immediately after its commencement into two trunks, the smaller of which leads forwards and gives forth those arteries which in other animals arise from the cross of this artery; and the other, which is longer in diameter, inclines backwards: these are usually termed the anterior and posterior aorta.

The beating of the heart may be felt on the left side, whence also the

* Hurltel D'Arboval's Dictionnaire de Médecine Vétérinaire.

pulse may be taken, or from the femoral artery which crosses the inside of the thigh in an oblique direction. In swine in a state of health the pulsations are from seventy to eighty in a minute.

DISEASED VALVES OF THE HEART.

This appears to be a more common malady than is generally suspected, for in repeated cases of sudden death, where a post-mortem examination has been made, there has been found fleshy excrescences or tumours on the tricuspid valves. We believe Mr. Cartwright, whose name we have already mentioned, was one of the first persons who drew attention to this disease. The only marked precursory symptoms appear to be inappetency and very shortly before death difficulty of breathing and evident distress. In one pig that died thus suddenly, Mr. Cartwright found several uneven warty excrescences, some as large as marbles, growing from the edge of the auriculo-ventricular valves of the left side; also several small papillary growths, all of which served three parts to close up the ventricular opening.

In another case he found a loose, jagged, warty excrescence growing from the whole surface of the tricuspid valves, closing up, in a great measure, the ventricular opening, and projecting at least half an inch into the left auricle. In a third the valves of the left auricle were thickened, schirrous, and presented a ragged uneven surface. The orifice of the ventricle was almost closed up by this diseased substance, and a portion had forced its way into the aorta. This disease was always found in the left side of the heart, and in no case did it extend beyond the circumference of the valves; the lining membrane of the heart always remained intact.*

BRONCHIAL TUBES.

Swine are very susceptible of *bronchitis*, and also liable to worms in the *bronchia*, both of which affections manifest themselves under the form of cough, inappetency, and loss of flesh. The former may be subdued by bleeding and cooling medicines, as sulphur, cream of tartar, or pulv. antimonialis: the latter almost invariably cause the death of the animal from the irritation they create and the inflammation which is thus set up.

INFLAMMATION OF THE LUNGS.

This disease is perhaps more generally known under the term of *rising of the lights*: it is one of the most prevalent and too often the most fatal of all the maladies that infest the sty. It has been supposed by some persons to be contagious, by others to be hereditary, but there does not appear to be any actual foundation for either of these opinions. By far the most probable supposition is, that it arises from some atmospheric influences or agencies which create a tendency to pulmonary affections, and these, acting upon a system heated and predisposed to disease by the mode of feeding adopted in most piggeries, give a serious and inflammatory character to that which would otherwise be merely a simple attack of catarrh; or it may arise from some irritating influence

* The Veterinarian, 1841.

in the food itself, or from damp, ill-ventilated sties: whatever be its cause, it generally runs through the whole piggery when it does make its appearance. The prominent indications of disease are loss of appetite, incessant and distressing cough, and heaving at the flanks.

As soon as the first symptoms are perceived the animal should be bled; the palate perhaps will be the best place in this case to take blood from; purgatives must then be given, but cautiously; Epsom salts and sulphur will be the best, administered in a dose of from two to four drachms of each, according to the size of the animal. To these may succeed sedative medicines:

Digitalis	.	.	two grains.
Pulv. Antimonialis	.	.	six grains.
Nitre	.	.	half a drachm.

forms a very efficient and soothing medicament for moderate-sized pigs, and will often produce very satisfactory effects; cleanliness, warmth, and wholesome cooling nutritious food, are likewise valuable aids in combatting this disease. But whatever measures are taken they must be prompt, for inflammation of the lungs runs its course with rapidity and intensity, and while we pause to consider what is best to be done, saps the vital energies of the patient.

In Wurtemberg there is a law of warranty for this disease, extending over a period of four weeks and three days.

Columella advises the insertion of a piece of *lung-wort* into the flaps of the ears of swine affected with disease of the lungs. We should be sorry to rely solely upon the effect of this "simple but efficient remedy."*

PLEURO-PNEUMONIA.

This disease often breaks out among pigs as well as horses, cattle, and sheep, and commits great devastation. We shall quote some accounts of its progress, treatment, and post-mortem appearances given by English and foreign veterinarians, by whom it is classed under the head of

EPIDEMICS.

M. Saussol narrates that during the summer of 1821 nearly all the swine in the neighbourhood of Mazamet were attacked by a violent and mortal disease that spared neither age nor sex, fat nor lean. He rates its ravages at about one-fifth of every four hundred patients.

The first symptoms were inappetency, thirst, dulness, groaning, and seeking of moist places; then followed hardness of the belly, heat of the skin, constipation, diminution of the urine, difficulty of respiration, heaving of the flanks, and short cough; the eyes were full of tears and the mucous membranes inflamed. All these symptoms came on in the course of twelve hours. If the disease continued the succeeding symptoms were still more alarming; the animals begun to stagger about, the limbs were stretched out in an unnatural position, rattling in the throat came on, they supported themselves against the wall, and only fell to die a few minutes afterwards. Death usually came about the third day, and was in some cases preceded by convulsions of the face and extremities.

* Columella's Husbandrie.

Treatment.—Copious bleedings from the *sacro-coccygean* arteries and veins, or if these did not yield blood enough, amputation of the tail, hot baths, a seton covered with blistering ointment inserted in the chest, camphorated and laxative drenches, and a decoction of borage, mallows, and lettuces, slightly acidulated, to drink.

Causes.—Exposure to the heat of the sun, want of water, feeding on dry plants; returning home in the evening exhausted, receiving a hearty feed, and being then shut up in ill-ventilated sties without drink until morning.

Preventive treatment.—Troughs of acidulated nitrated water placed in the sties and frequently renewed; non-exposure to the heat of the day, means of bathing, bleeding, cleanliness, and ventilation; moderate feeding, and gentle exercise after the sun had set. These precautionary measures, M. Saussol says, arrested the progress of the disease.

Post-mortem appearances.—The thoracic cavity was filled with bloody limpid fluid; the lungs much inflamed; the pleura thickened, inflamed, and injected; the diaphragm covered with black patches of the size of a shilling; the mucous coat of the intestines slightly inflamed; the wind-pipe and bronchial tubes full of reddish froth; the brain covered with reddish serosity.*

The next account we come to gives a description of a somewhat different epidemic which occurred in Aveyron and its environs, attacking both the respiratory and digestive organs, and running its course with astonishing vigour and rapidity, frequently sweeping off all the inhabitants of a piggery in from twelve to fourteen hours, and in the more virulent cases in less than half this time.

Symptoms.—In the worst cases these are sudden loss of appetite, small and frequent pulse, haggard eyes, the conjunctiva inflamed, the mouth open, red, and filled with foam, the respiration laborious, plaintive cries, convulsions, palsy of the hind limbs, and involuntary discharge of highly fetid fæces. Death here is the inevitable termination, and that in a short time. But where the progress of the disease is less rapid the symptoms assume a milder form, and medical aid is available and often beneficial. Pregnant sows escape the attack of this malady, but as soon as they have farrowed they lose this immunity and they and their young take it. It also seems to spare leprous swine. It appears at all seasons of the year, but is most malignant in the summer and at the commencement of autumn. There can be no doubt as to its contagion, and from some experiments made, it can be reproduced in other animals by inoculation, particularly in sheep. The flesh of pigs that have died of this disease has been given to dogs and eaten by them without producing any bad effects.

Causes.—Unwholesome food, ill-ventilated sties, want of attention to cleanliness, exposure to heat, wet, or cold, are the predisposing causes; and probably some miasmatic influence develops the disease.

Treatment.—In the most virulent cases almost all modes of treatment are unsuccessful; or if they do succeed in rescuing the animal from death, he generally falls into a state of marasmus, or becomes paralytic. In the milder cases the following means have often proved efficient:—Seton in the chest; a decoction of sorel, with camphor, nitre, and calomel, as a drench; emollient injections, slightly acidulated; stimulating

* Journal de Médecine Vétérinaire, 1832.

frictions of the dorsal and lumbar regions, or bathing these parts with hot vinegar; and water thickened with oat or barley meal as the sole diet and drink. Venesection is here dangerous, tending only to undermine the strength of the patient, this disease being evidently one which alters, decomposes, and vitiates the blood. Acetate of ammonia, administered in doses proportionate to the size of the patient, has been of service. Purgatives should be avoided, as they are of very uncertain benefit. Directly an animal is attacked he should be removed from the others, and placed in some comfortable place.

Prevention.—Strict attention to diet, cleanliness, ventilation, and comfort; and a plentiful supply of clean water, both for the animals to drink and to bathe themselves in. In cold and rainy weather they should be kept in their sties; and during the heat of summer their drink should be slightly nitrated, acidulated, or salted. Whey is an excellent thing for those that are weakly. Small doses of camphor and nitre, with the addition of a few grains of calomel, administered in some cooling vegetable decoction, is a useful preventive. If one pig is attacked he should be removed, and the others taken out while the sty is well fumigated.*

In 1838 we have accounts of an inflammatory epizootic among pigs, rapid and fatal in its course, and attacking by preference store pigs rather than those put up to fatten.

Symptoms.—Prostration of strength, difficulty of breathing, discharge from the mouth and nostrils, constant cough, and reddish hue of the skin. These went on increasing in intensity until death put a period to them, which usually occurred in from three days to three days and a-half after the commencement of the attack.

Treatment.—Bleeding and laxative medicines, stimulating frictions of the trachea and parietes of the thorax, seemed to be the most efficient remedies. Doses of tartarized antimony and Hydrarg. Sub. Mur. in three grains of each, administered every twelfth hour, produced vomiting, and appeared to give ease. Sulphate of magnesia relieved those cases in which there was constipation.

The causes seemed obscure. The epidemic prevailed in the summer; but whether it arose from the warmth of the weather, from want of a sufficient supply of water, or from dry and heating food, was not at all evident.†

Paulet has described a very similar epidemic among swine, which frequently prevails in one or the other of the *arrondissements* of the south of France. He describes it as highly inflammatory, rapidly going on to gangrene, and exceedingly contagious, but is at a loss to what cause to attribute it.

The precursory symptoms are, according to him, restlessness, cough, loss of appetite, dulness, and a weak tottering gait. These gradually go on increasing in intensity until the seventh or eighth day, when they have become very marked. Then alternations of heat and coldness of the body come on; the ears droop and are cold, the head is heavy, and the tongue becomes discoloured; the breath is fetid, and there is a copious discharge of mucus from the nostrils. The skin is tinged with red, but the hue is not very evident excepting under the belly: the ani-

* Recueil de Médecine Vétérinaire, 1834.

† Veterinarian for 1838.

mal appears to be in great suffering, and cries out pitifully. This general inflammation of the integuments rapidly goes on to gangrene, which alteration is evidenced by the livid violet hue of the diseased surfaces. Death then rapidly follows.

He too prescribes bleeding, and from the ears and veins of the belly, while many authors condemn it as debilitating. The only thing he recommends besides is thin oatmeal gruel, acidulated with white-wine vinegar; for he appears to consider the malady to be so fatal that medical treatment avails nothing against it. Here, however, we cannot but deem him wrong; many of the most virulent, and, if neglected, fatal of the diseases to which our domesticated animals are subject, will yield to the influence of a judicious course of treatment, and many a valuable animal has been saved by the skill and attention of a veterinary surgeon. We should recommend laxative drenches, stimulating frictions, warmth and cleanliness, and a seton in the chest.

In the epidemic which prevailed in 1841 throughout the greater part of England, swine were affected, as well as horses, cattle, and sheep, and often took it before any of the rest of the stock, but in general had it more mildly. This malady was of a highly contagious, inflammatory character, and affected chiefly the mucous and secretory tissues. When once it entered a farm-yard it spread rapidly, until every ox, sheep, or pig was infected, and in some instances it passed to the human being. Damp, wet weather appeared most favourable to its development; and from all accounts it seems to have arisen from some atmospheric agency.

Symptoms.—Lameness of one or more of the feet, accompanied with heat around the hoof and lower part of the leg; discharge of saliva from the mouth and nostrils; champing or grinding of the lower jaw; ulceration of the mouth and tongue, extending even to the snout; dullness, inappetency, constipation, rapid emaciation, and cough.

Treatment.—The ulcerated portions of the feet and the detached pieces of horn should be carefully pared, and the parts daily washed with a solution of blue vitriol, or smeared with warm tar; the mouths also dressed with a strong solution of alum; and from an ounce and a half to two ounces of Glauber salts, dissolved in water, and given in their food. Where the malady was attacked in its onset, these simple remedies sufficed to produce convalescence in from fourteen to one-and-twenty days.

Post-mortem appearances.—There were patches of inflammation throughout the whole of the intestines, both externally and internally; the liver was sound; the heart flabby and soft; the lungs shrivelled, flattened, and diminished to one-half their natural size, and in some cases hepatized; the diaphragm, pleura, and bronchial tubes of a greenish hue, and evidently gangrenous.

The flesh of pigs that had died of this epidemic was eaten by some persons without their suffering any ill effects; nevertheless the experiment was hazardous.*

* Veterinarian for 1841.

CHAPTER VIII.

Anatomy of the Stomach—Gullet—Intestines—Duodenum—Jejunum—Ileum—Cæcum and Colon: Diseases to which these parts are liable—Enteritis—Colic—Diarrhœa—Garget of the Maw—Anatomy of the Liver and Spleen: Splenitis—Rupture of the Spleen—Absorption of the Spleen—Peritoneum—Worms—The Bladder and its diseases—Protrusion of the Rectum.

THE GULLET.

THE gullet, or *œsophagus*, is a musculo-membranous tube, commencing at the pharynx, passing down the throat on the left side of the wind-pipe, entering the chest in company with that tube, penetrating through the folds of the diaphragm, and terminating in the stomach through an orifice termed the *cardia*.

THE STOMACH.

The stomach of the hog is a much more simple apparatus than that of the ox and sheep; it is a truly omnivorous one, and beautifully adapted by its pyramidal appendage and glandular structure, as well as by the villous mucous membrane with which it is lined, for the digestion of the heterogeneous food which it is destined to receive, being perhaps more analogous to that of the horse than to any other animal. In form it is globulous. Its large blind cavity is very voluminous, and is surmounted in front by a hood-like appendage. The narrow long portion which abuts on the pylorus greatly resembles this hood-shaped appendage. On each side of the cardia are two transversal folds, and the cardia itself is half way between the pylorus and the large cavity.

The stomach has three coats,—the outermost, or *peritoneum*, which constitutes the common covering of all the intestines; the muscular or fibrous coat, which acts upon, and mingles the food, and prepares it for digestion; and the mucous or villous coat, which is peculiarly developed in the pig, and into which open the mouths of numerous little vessels, conveying the gastric juice to the semi-digested food, and by its action converting it into a pulsatious fluid, commonly called *chyme*.

THE INTESTINES.

The intestines of the hog bear a stronger resemblance to those of the human being than we find in any other animal. They are sixteen times the length of the body of the animal, and the proportions of the small intestines to the large are as three to one. They are composed of four coats or layers. The outer or peritoneal one is formed of that membrane which invests and retains in its proper position every portion of the contents of the belly. The second layer is muscular, and by its action propels the contents of the stomach gradually onwards. The office of the third is to lubricate the innermost coat, and for this purpose, it is supplied with numerous glands surrounded by cellular tissue. The fourth or lining coat is soft, villous, and in a healthy state always covered with mucus. The food, having been sufficiently converted into chyme by the action of the stomachs, is gradually propelled through the pyloric orifice by

THE DUODENUM,

or first intestine, where it is submitted to the influence of two fluids, the one secreted by the pancreas, the other by the liver, and the combined action of which separates the nutritious from the worthless portion, causing the former to assume the appearance of a thick whitish fluid, and the latter that of a yellow pulpy substance. It next passes into

THE JEJUNUM AND ILEUM,

where it undergoes still further alteration, and whence a considerable portion of it is taken up by the lacteal vessels which open into these two small intestines, and conveyed away to nourish the frame, and become mingled with the blood and supply the waste in it. These intestines are of equal diameter in the pig throughout their whole extent, and the termination of the jejunum and commencement of the ileum is by no means distinctly defined; the latter is, however, longer than the former, and opens into

THE CÆCUM,

with a valvular opening close to the aperture into the colon. The cæcum is a kind of bag supplied with numerous secretory glands, which furnish it with a fluid which once more acts upon those portions of the digested food which reach it, extracting from them any nutritive portions which may chance still to remain. The matter having reached the base of this intestine, is returned by the muscular action of its coat, and being prevented by the valve from re-entering the ileum, passes into

THE COLON,

the longest of the large intestines, some of the convolutions of which equal the stomach in size, while others are as small as the small intestines. Here the watery parts of the mass are extracted, and the residuum or hard fecal portion is retained for awhile, and finally expelled through the *rectum*. It will be readily imagined that this complicated and beautiful process must occasionally become deranged by various causes, and that hence will arise different diseases of a more or less serious nature. This is, however, less the case in swine than in most of our other domesticated animals, from the circumstance of their stomachs and intestines being prepared by the softening power of their highly mucous villous lining for the reception and digestion of a heterogeneous mass of food, which to other animals would be actually poisonous; rendering it evident that, although the hog in a state of nature is a herbivorous animal, he was also destined to become omnivorous for the service of man.

ENTERITIS.

This disease consists in inflammation of one or more of the coats of the intestines, and is capable of being produced by various irritating causes, as the foul air of badly ventilated sties, unwholesome food, &c.

The symptoms are dulness loss of appetite, constipation, spasms, or

convulsions, continued restless motion, either to and fro, or round and round, staggering gait, evident symptoms of suffering.

The most successful treatment is warm baths, dry litter, and general warmth and comfort; and internally, purgatives and enemata. Castor oil, calomel, or rhubarb, are the best purgatives for cases of this nature, and the enemata should be of an emollient oleaginous nature. The diet should be restricted to the simplest and lightest food; oatmeal porridge, skim-milk, or whey are the best things.

The following are cases of gastro-enteritis, apparently combined with a cerebral affection, which Mr. Cartwright, from whose observation of disease we have so frequently drawn, gives in the "Veterinarian" for 1841:—

"On the 27th of June last, I was sent for to see a small pig belonging to Mr. Hont, of Whitechurch. It was about three months old, appeared to be unwell, and refused its food. It forced its head against any thing it came in contact with, and sometimes would walk round and round repeatedly. It stood up most of the day, and was much swollen. Open the bowels with castor oil.

"28th.—No better. It now lay down on its breast and fore legs, and continued in this posture the greater part of the day. Its respiration was increased. Repeat the aperient, and administer enema. In the course of the afternoon it died.

"*Examination.*—On the villous portion of the stomach, within the greater curvature, was a patch, at least three inches in circumference, of intense inflammation of the mucous membrane of the intestines. The inflammation did not occupy one continuous space, but there were patches of it from four inches to a foot in size in places that were otherwise tolerably healthy. The inflammation was also in irregular circular streaks round the intestine, of one-eighth of an inch in width. There was a small similar patch of intense inflammation on the mucous coat, at the blind end of the cæcum, as well as in the stomach.

"The rectum had been ruptured by the owner by too forcible clys-tering. There was, perhaps, half an ounce of serum within the pericardium. The brain and all other parts were sound. A portion of fecal matter had oozed out through the ruptured part of the rectum, and there was nearly two quarts of effusion in the cavity of the abdomen.

"*Observations.*—It appears that three large lettuces had been eaten by this pig the day before, when he appeared quite well. Did they cause the disease in his head (if any,) and in the bowels? What produced the violent inflammation in his stomach? He had had no other medicine than the Ol. Ricini to produce any fatal purgative action, and his bowels were quite relaxed."

"In the month of May last, I was called to look at a pig of Mr. Kempster's that had been ill a couple of days. It was lying down in a high state of fever, and breathing laboriously; and would not, I think, have lived long. It had been in a similar state most of the day, and had a large quantity of pulv. jalapæ given to it. I ordered it to be killed.

"*Examination.*—I could discover nothing amiss except a patch of inflammation, as in the last case, in the stomach, and some in the intestines."

"I was sent for on December 20th, 1835, to see two pigs belonging to a Mr. Parker, of Whitchurch.

"*Symptoms.*—In one there was great stupor, and indifference to move about. He was very weak and would fall on his knees or on his side; in short, we could do what we would with him. The other was turning round half his time, or forcing his head against any thing he came in contact with. Sometimes he would fall upon his knees, or shake his head convulsively. The head and ears were hot, the pulse very quick, the respiration natural. The abdomen of one was very slightly distended, and the sides of the other were flat. I advised that both should be killed.

"*Examination.*—The stomach of the first was filled with half-digested meat, composed of ground oats, barley, and potatoes, but there was no distention or disease in it. The small intestines looked inflamed, and on laying open the abdomen, and cutting into them, they were found to be so. On the mucous membrane of the large intestines there were many eminences or tubercles, similar to those that are found in the stomachs of horses and produced by bots, with a small cavity in their centre. The lungs were congested in their anterior small lobes, but otherwise sound.

"The small intestine of the other was also inflamed, but not so much as in the first pig; there was likewise a great deal of secretion in them. All other parts of the body were sound; I had no opportunity of examining the head.

"These pigs ate their supper over night as well as usual, as may be known by their stomachs being filled. On the Thursday preceding, they had had thrown into the tub of meat from which they were fed a quantity of refuse brine, made of salt and saltpetre. They had been used for curing some bacon, and on the next day the servant said the pigs had not eaten their meal *as well as usual*.

COLIC.

The hog is frequently attacked by this malady, which generally arises from unwholesome food, cold, or wet filthy sties; and is evidenced by restlessness, cries of pain, rolling on the ground, &c. A dose of castor oil proportionate to the size of the patient, with perhaps a little of ginger in it, and administered in warm milk, will generally give speedy relief; or if the first should not, the dose must be repeated. Some practitioners recommend Glauber's or Epsom salts, but we consider oleaginous purgatives to be best adapted for attacks of colic.

DIARRHŒA.

This is a disease very common among all our young domesticated animals, and one that is also repeatedly met with in older ones; a scanty allowance, or unwholesome food will produce it, as will also over feeding or too nutritious diet. It consists in a frequent discharge of the fecal matter in a thin or slimy state, but not actually altered, and arises from inflammation or congestion of the mucous lining of the intestines. What we conceive to be an attack of diarrhœa, is often only an effort of nature to throw off some offensive matters, and will cease of itself in the course of twenty-four hours; but where it goes on for any length of time, it must be taken seriously in hand, as it will other-

wise weaken the animal and impair its value. The best remedy for it is the compound commonly called calves' cordial, viz. :—

Prep. chalk	one ounce.
Pow. catechu	half an ounce.
Pow. ginger	two drachms.
Pow. opium	half a drachm.
Mixed and dissolved in half a pint of peppermint-water.	

From half an ounce to an ounce of this mixture, according to the size of the animal, should be given twice in the day; and strict attention paid to the diet, which should consist as much as possible of dry farinaceous food.

GARGET OF THE MAW.

This is a disorder arising from repletion, and is found alike in older animals and in sucking pigs. Its symptoms strongly resemble those of colic. The remedies, too, are purgatives. Epsom salts is here, perhaps, as good a thing as can be given, in doses of from a quarter of an ounce to an ounce. It might as well be termed *indigestion*, for such it actually is, the stomach being overloaded with food. In sucking pigs it usually arises from the coagulation of milk in the stomach.

THE LIVER.

This organ in swine does not appear to be so subject to disease as it is in most of our other domesticated animals; we have only, therefore, to glance at its use and anatomy as we pass. It is smaller in swine than in sheep, and larger than we find it in the dog, in accordance with that anatomical law, which seems to be in force in all animals; namely, that the size of the liver shall be in inverse proportion to that of the lungs. It is situated in the anterior part of the abdomen, and its upper surface rests against the concavity of the diaphragm. Its office is to receive the blood that is returned from the intestines, separate from it and secrete the fluid termed *bile*, and then forward the residue of the blood onwards to the lungs, where it undergoes the usual aërating process, and becomes transmuted into arterial blood.

The fluid or *bile* thus secreted, when in a healthy state, and not in undue proportion, stimulates the mucous membrane, and increases the peristaltic motion of the intestines, excites the secretion of that mucus requisite to preserve these parts in a healthy state, hastens the process of separating the nutritious from the innutritious parts of the food, and facilitates the escape of the fecal matters. It also acts chemically upon the various substances which are devoured by the animal, and is the chief agent in neutralizing the acidity which some of these would otherwise create. The liver of the pig has four distinct lobes.

THE SPLEEN.

In the hog the spleen is very long, and nearly of a uniform breadth and thickness throughout its whole extent. It lies on the left side of the abdomen, and is attached to the stomach by the folds of the epiploon. Its texture is almost like that of a sponge in appearance, consisting of innumerable cells of every size and form, yet it is firm to the touch. In colour it is a dark, deep reddish brown.

There has been much dispute as to the functions and use of this organ. Some persons, arguing from its situation, contend that it is a powerful agent in the process of digestion; but this is strongly negatived by the fact, that it has been removed from some animals which have existed for a considerable time afterwards, without apparent injury to that function. Others, again, and with more probability, assume that it has to do with the colouring and conversion of the chyle into blood as it passes through the mesentery, where it becomes mixed with the red coagulable fluid furnished by the spleen. But with these physiological questions we have at present nothing to do: our purpose is simply to consider it with a view to understanding and treating those diseases of which it is not unfrequently the seat. Little attention has hitherto been paid to them, probably from their symptoms being somewhat obscure; but, nevertheless, different morbid affections of the spleen are by no means uncommon among the lower domesticated animals. This viscus is often ruptured, distended with blood, inflamed, or softened, from the effects of different causes, but chiefly of damp, heat, or foul air.

SPLENITIS.

Swine suffering under this malady are restless and debilitated, shun their companions, and bury themselves in the litter. There is loss of appetite and excessive thirst, so excessive that they will drink up any thing that comes in their way, no matter how filthy. The respiration is short; they cough, vomit, grind the teeth, and foam at the mouth; the groin is wrinkled, and of a pale brownish hue, and the skin of the throat, chest, and belly (which latter is hard and tucked up,) is tinged with black.

The remedies are copious blood-letting, gentle purgatives, as Epsom or Glauber's salts, followed up by cooling medicines. Cold lotions of vinegar and water to bathe the parts in the neighbourhood of the spleen, or a cold shower-bath applied by means of a watering-pot are also efficacious in these cases.

Columella, in his quaint style, thus treats of this disease:—

“Also the pain of a distempered spleen uses to plague them; the which chiefly happens when there chances to be great droughts, and, as the Bucolic poem speaks—

When on all sides the apples scattered lie,
Each under its own tree;

for it is an insatiable cattle the swine, which beyond all measure eagerly seek after that which is sweet. They labour and are affected in the summer and early autumn with a swelling or growth of the spleen, from the which they are relieved if troughs be made of *tamarisks* and *butcher's broom*, and filled with water, and set before them when they are thirsty; for the medicinal juice of the wood being swallowed with the drink, puts a stop to the intestinal swelling.”

The great difficulty here is, how troughs can be made of the *museus* (butcher's broom.) In all probability the true meaning is, that the troughs should be lined with the branches of this plant; and the *tamarisks* signifies doubtless the *tamaricus e trunco* mentioned by Pliny, lib. xxiv. 9, where he speaks of canals and troughs being made of the

tamarix. Translators are given occasionally to make similar mistakes or alterations of text.

RUPTURE OF THE SPLEEN.

We quote this case from the "Veterinarian" for 1841 :—

"A pig belonging to Mr. Roberts of Whitchurch, died after having only been ill for a day or so, and that unattended by any definite symptoms. On post-mortem examination the spleen was found to be of about three or four times its natural size, and completely congested. In one place there was a small rupture surrounded with coagulated blood. All the other viscera were perfectly sound."

ABSORPTION OF THE SPLEEN.

This case is also derived from the same source, and we present it to our readers as a testimony of the different forms of disease which occur in the spleen of the swine.

"A fat pig, weighing fifteen score, was killed, and upon cutting it up, the spleen was found to be almost entirely absorbed. It was of the usual length, but not above half an inch in width or the eighth of an inch in thickness in any part, and weighed but seven drachms. What there was of it, however, appeared to be perfectly sound, and was surrounded by a considerable portion of adepts."

PERITONEUM.

This portion of the contents of the abdomen is composed of cellular tissue, and amply supplied with absorbent vessels; its office is to separate the different viscera from each other, to envelop them, and to attach them to and support them in their proper position. It is subject to attacks of inflammation, technically termed

PERITONITIS,

the symptoms of which closely resembles those of splenitis; and the causes too are very similar, being chiefly improper food, repletion, or exposure to extremes of temperature. Oleaginous purgatives are here the only ones which are admissible, and emollient clysters; great attention must also be paid to the diet, and nothing of an acrid or indigestible nature given to the animal. This disease is too often fatal, gradually wasting away its victim. The post-mortem appearances are as follows: the intestines have become so adherent to each other that it is scarcely possible to believe that any false membranes were ever interposed; the peritoneal surfaces present evidences of inflammation, and are often covered with confluent ulcerations resembling those seen in glanders of the horse; there is considerable inflammation of the muscular coat of the intestines, and the whole of these parts are thickened and corrugated.

WORMS IN THE INTESTINES.

These entozocaria are very troublesome in swine, and often exceedingly fatal. The *spiroptera strongylina* is of the kinds most common to

the hog, but the *ascarides tænia* and *echinorhinc* are likewise often found in considerable numbers.

The presence of worms may be inferred when the animal eats voraciously and yet continues lean and out of condition; coughs, runs restlessly about, uttering squeaks of pain, becomes savage, snapping at his companions and destroying all rabbits and poultry that come in his way. The excrements are generally hard and highly coloured, the eyes sunken, the animal becomes daily more debilitated, and frequent attacks resembling colic tend still further to weaken him. Too often he dies; for before these symptoms have been noticed the evil has generally attained to such a height as to be beyond the power of medicine; for these parasites, and the *echinorhinc* especially, multiply with incredible rapidity.

Drastic purgatives constitute the most efficient means of combating worms; but they must be cautiously administered, as they are but too apt to dissolve and force away with them the lining mucus of the intestinal canals. Turpentine is exceedingly destructive to worms, and, although to many of our domesticated animals a dangerous medicine, it may be administered with perfect safety to the hog. Common salt may also be given with advantage, and should be mingled with the food. Nor must it be supposed that because no worms are seen to come away from the animal the treatment may be discontinued, or that there are none; hundreds of them die in the intestines, and there become digested and decomposed, and go through the same processes as the food.

THE BLADDER.

This organ seems to be but little subject to disease in swine. Its position beneath the rectum and genital organs contained in the pelvic cavity protects it in all animals from external injuries; and the pig not being exposed to those causes which render the horse and dog peculiarly liable to disease of the bladder, namely, speed, long and fatiguing exercises, &c., seems to be comparatively exempt from it.

There is, however, a case narrated in the "Veterinarian," by Mr. Reid, V. S., which we shall quote.

VESICAL CALCULI.

"A barrow-pig that to the seventh month had manifested perfect health, from that period fell rapidly away (although its appetite remained unimpaired,) so much so in fact that in two months more it was a mere bag of bones, and the owner had it destroyed. He attributed this decline to a difficulty in passing its urine, which distressed the animal to such a degree that every time it wanted to stall it quite moaned with pain, rolling upon its back, arising, and again posturing itself for stalling, arching its spine, and making violent efforts, which too often were ineffectual. At other times, and indeed oftenest, he after much straining succeeded in passing a little urine, but this was speedily followed by fresh efforts. Occasionally, after having rolled about and laid on its back, it obtained relief by a flow of urine in a full stream. The urine was at all times perfectly clear."

This account was sufficient to draw Mr. Reid's attention to the presence of vesical calculi. He regretted that he had not been called in

during the life of the animal, that he might have made it the subject of operation, and requested permission to examine the carcass.

The bladder was half full of limpid urine, in which floated the stone. The internal coat of the bladder about the inferior part exhibited slight blushes of inflammation. All around the neck it was deeply inflamed, and thence the reddening spread about an inch into the urethra. The peritoneum also exhibited a light tint.

INVERSION OF THE BLADDER.

A sow littered in the morning and brought forth ten pigs without any apparent difficulty, and immediately afterwards something resembling the bladder, and which appeared to be about half full, came out. The owner seeing that it did not come away, became alarmed and sent for the pig butcher, who said it was the womb, and that it must be put back, which he accordingly endeavoured to do, and having passed two or three stitches of small twine across the labia to retain the parts, left the animal. Mr. Neale, V. S. of Burbage, happening to hear of the occurrence, called to see the sow. He found the vagina considerably protruded, or at least that there was a protrusion of the size of a man's fist, and in a sloughing state there. She appeared, however, in good condition, got up without apparent pain or difficulty, and was sucking her young well. The urine was flowing drop by drop. As the owner declined having any thing done to her, Mr. Neale ordered the parts to be bathed with a decoction of bark. Four months afterwards she was killed for bacon, and weighed 160 lbs. Upon opening her the uterus was found to be perfectly healthy, the vagina as clean as possible, and the tumour reduced by sloughing to the size of a lemon; the bladder was completely gone. The kidneys were full of white purulent matter of about the consistence of cream. The uterus led directly from the kidneys to the protruded part, at the inside of which and just below the anus was a formation of matter about the size of a hen's egg. There was not the slightest trace of inflammation in any of the surrounding parts.*

PROTRUSION OF THE RECTUM.

This is an evil of not unfrequent occurrence in swine, arising chiefly from obstruction of the intestines. Where the cause is simply obstruction an operation will remedy it; but as the obstruction is too frequently attended with rupture of some of the intestines, it will perhaps be as well to have the animal slaughtered at once, especially if it is in tolerably good condition.

HERNIA.

There is little doubt but that umbilical and congenital hernia are of frequent occurrence among swine; but as yet the attention devoted to the diseases of these animals has been so slight that we dare not venture positively to assert the fact.

* The Veterinarian for 1838.

CHAPTER IX.

The Skin and its Diseases—Gangrenous Erysipelas—Lice—Leprosy—Mange—Measles—Desquamation of the Skin.

THE SKIN.

THE skin of the hog, like that of most other animals, is composed of three separate parts or layers. The first or exterior of these is the *cuticle* or scarf skin, which covers the whole surface of the body and protects the more sensitive parts from the injuries which might result to them from immediate contact with external agents. It is a thin, tough, callous texture, perforated with innumerable holes or pores, through which pass the hairs and bristles, and whence exude those transpirations by means of which the body throws off all vapours injurious to the system. Chemical analysis has proved it to be chiefly composed of gelatine, and consequently insoluble in water of common temperature. This layer is considerably tougher and denser in the hog and other of the pachydermata than it is in the horse, ox, and most of our domesticated animals.

Beneath this is the *rete mucosum*, a soft expansion of tissue which overspreads, and can with difficulty be separated from the layer below it. Its purpose appears to be to protect the terminations of the blood-vessels and nerves of the skin, which it in a manner envelopes or covers. This layer determines the colour of the body and of the hair.

The third and undermost part is the *cutis vera* or true skin, an elastic texture composed of innumerable minute fibres crossing each other in all directions, fitting closely to every part of the frame, yielding by its elasticity to all the motions of the body, and interposing its dense, firm structure between the more vital parts of the system and external injuries. Innumerable blood-vessels and nerves pass through it, and appear upon its surface in the form of papillæ; it is in fact far more sensitive than the muscles or flesh.

The skin varies in density in different breeds of swine. In some of the large, old breeds it is thick, coarse, tough, and almost as impenetrable, in comparison, as the hide of a rhinoceros; while in many of our smaller breeds, and particularly in those which have a considerable admixture of Asiatic blood, and in the Chinese pigs themselves, it is soft, fine, and delicate, and bears no slight degree of resemblance to the skin of the human being. It is not to be wondered at that a structure so delicately organised as the one we have been describing should be subject to disease. In the hog it is peculiarly so; many of the most serious maladies to which he is subject have their seat in the skin: it were a point well worthy of study to inquire into the reason of this fact, but as the present work is devoted to practice rather than theory, we must leave it to abler hands, and pass onwards to a consideration of some of the most prevalent diseases of the skin in swine.

GANGRENOUS ERYSIPELAS.

This disease which is frequently spoken of by the ancient writers, as prevailing to a greater or less extent, and often almost as an epidemic

among sheep and swine, is now of rare occurrence. Poulet thus describes the symptoms:—

“The first of these, which last some five or six days, are uneasiness, inquietude, depression, loss of appetite, and inertness. About the seventh or eighth day these gradually increase in intensity; the limbs totter, the body is alternately hot and cold, the ears droop and are cold, the head appears heavy, the tongue is discoloured, the breath fetid, a thick mucus flows from the nostrils, and the whole of the skin becomes tinged with an erysipelatous redness, which is most evident under the belly; the animal utters almost incessant screams of pain. This inflammatory state of the integuments rapidly merges into decided gangrene, and the whole of the diseased surface becomes of a livid blue or violet hue. The skin is first covered with blisters containing a thin reddish watery fluid; and as these break the gangrenous dark coloured scabs are formed. The disease is however by no means of so fatal a character in swine as it is in sheep, probably from the former being the stronger animals. A little blood should be taken from the ears, once at any rate, and the bleeding should be repeated if it appears at all necessary. A dose or two of Epsom salts, cooling drinks slightly acidulated, and strict attention to diet, and cleanliness, are generally all that will be requisite. Should the skin appear to be very irritable, a little sweet oil may be rubbed over it, or some sulphur made into a kind of ointment with sweet oil or palm oil; but local applications are not generally requisite.”

Exposure to great heat or cold, or any sudden transition from one extreme of temperature to another, are supposed by some authors to be the causes of this disease; while others, and we think with justice, attribute it to unwholesome or putrid food, and to general inattention and neglect.

LICE.

Pigs, when allowed to wallow in the mire, and to dwell in filthy sties, are very apt to engender these disgusting vermin, which eat into the skin and render it scabby and ulcerated, and by the irritation they keep up worry and fatigue the animals, and effectually prevent them from thriving. Eric Viborg states that these vermin sometimes burrow their way into the flesh and come out through the eyes, nostrils, or mouth, or have even been known to be voided in the urine.

The first step to be taken towards effecting a cure is thoroughly to cleanse the skin from every particle of dirt, and to clean out and white-wash the sties and put in fresh dry litter.

Mercurial ointment, turpentine, or tobacco-water, are the most efficient agents in the destruction of these unwelcome parasites. A little sulphur or Ethiop's mineral and bay-salt may be given internally.

The preventive means are strict attention to cleanliness both in the sties and in the animals themselves. Whenever a pig is observed to be lousy, which will quickly be perceived by his rubbing himself against the gates, trees, and walls, he must be immediately separated from his companions, or they too will become infested with lice, if they are not already so.

Parkinson is of opinion that “the cause of vermin infesting animals clearly arises in a general way, from bad feeding, which occasions

weakness of the blood ; for," says he, "if an animal be ever so lousy, by giving him strong food for a few days the vermin will disappear, probably because the rich blood is poison to them." He considers that a free access to water for bathing, and also occasional exposure to heavy rain, is not only necessary to the general health of swine, but a most excellent preservative against vermin.*

LEPROSY.

This disease has apparently existed in swine from the remotest periods, and Tacitus gives it as his opinion that it was because the hog was subject to leprosy that the Jews were forbidden to eat of its flesh. It consists in the development of certain vesicles, or whitish granulations, in all parts and portions of the cellular tissue; which vesicles have been proved to be neither more nor less than a species of worms termed the *cysticercus cellulosa*, supposed by some French authors to be of the same species as that found in the brain of sheep. There are however considerable differences between these two. The *cysticercus* is found in all the cellular tissues and soft parts throughout the whole of the body; in the fat, in the adipose matter, in the interstices between the muscles, in the viscera, and, in short, in every crevice into which they can insert themselves. The thigh or ham has been mentioned by some authors as the principal seat of these vesicles, but they are also found on the shoulders, around the jaws, along the neck and belly, and even underneath and around the root of the tongue, where alone can any outward lesions indicative of leprosy be in general discovered; and even here they are not constant, but are chiefly evident in those animals in which the disease has attained to a great height. The progress of leprosy is very insidious, and the early symptoms so little marked that a practised eye only can detect them.

In the onset all that is observable is a certain marked stupidity or obstinacy in the animal; a state of languor and apparent general debility; an evident thickening of the skin; a slight adhesion of the bristles; a tendency in the hair to fall off, caused by the development of a greater or less quantity of those vesicles of which we have spoken, as being scattered in different parts of the fatty tissue, either on its surface or in the interstices of the muscles; under the coats of the viscera, or on the sides of the tongue.

In its successive progress this disease attacks the animal economy more or less profoundly without the functions appearing otherwise troubled. There is ulceration of the cellular tissue, and even of the organs that surround or penetrate it: the animal does not however appear to be generally and seriously ill. Far from losing his appetite, he is occasionally extremely voracious. He does not appear to suffer in the lungs; his breath is not embarrassed, nor is his voice hoarser than usual.

Such is at least what may be observed to take place when the leprosy vesicles are not numerous. It is when they increase in quality and the disease increases that they begin to affect the health of the patient. He then becomes indifferent to every thing; moves about slowly; totters as he walks: his eyes are dull; the buccal membrane is pale, and some-

* Parkinson's Live stock, vol. ii.

times strewed with violet spots. The expired air is fetid, the breathing slow; the pulse small and irregular, the bristles easily plucked, and sometimes a little blood accompanies them. Strength begins to abandon the patient; he can no longer sustain himself on his hind legs; the posterior part of the trunk becomes paralyzed, the body exhales an unpleasant smell; the skin is thicker, and the cellular tissue is raised in different parts, especially about the kernels of the neck. There is swelling about the roots of the hair, which often proceeds to ulceration; the skin comes off in patches; large tumours are developed; the teeth are ground convulsively together; the tongue is dark coloured, hot, thickened, and covered with slime; the body swells; the animal utters feeble cries of pain, and seldom survives many hours.

This is a very obstinate disease, probably from its having usually taken so great a hold of the system before it is suspected, and numerous have been the medicaments recommended for it. Antimony, sulphur, small and repeated doses of Epsom salts, and general bleedings, seem to be the course of treatment most likely to be attended with success; and these must be aided by strict attention to diet and cleanliness; cooling wholesome food alone should be given, and water, in which barley-meal has been dissolved. Nothing of a rich or heating nature should be allowed to come within reach of the animal. As external applications, mercurial ointment may be moderately applied to the ulcerated parts, or the common mange ointment composed of sulphur and antimony.

In all probability the reason why this and many other diseases of swine have hitherto been regarded as incurable, is that men of science, educated veterinarians, have as yet given but little of their attention to these useful animals, and deemed the study of their diseases and of the means of treating them beneath their notice. Nor is the owner without his share of blame, for he too often either abandons the poor brute to its fate, or calls in the aid of the pig-butcher or some ignorant empiric.

In France the pig-gelder, or *languyeur des porcs*, is the privileged medical attendant of swine. He attends daily wherever there are any pigs to be sold, and examines the tongue to see that in its frænum there is no worm or cysticercus, the presumed cause of leprosy. Should he find, or fancy that he finds, some little vesicles on the sides of the tongue, he pierces them with his scissors, and bruises them with a silver coin, a proceeding which, according to him, will infallibly cure the animal and effectually preserve it from leprosy. But should it, as is too often the case, unfortunately happen that in the struggle attending this operation the animal receives some serious injury, of which it afterwards dies, the *languyeur's* excuse is, that the *bechigos* or vesicles were in a state of inflammation, and consequently incurable when he first saw them.

There have been numerous opinions advanced relative to the predisposing causes of leprosy; some authors attribute it to exposure to the inclemency of the weather, insufficient food, and damp marshy localities; and urge in support of their opinion that the disease was much more prevalent and fatal when swine were turned into the woods and forests during certain periods of the year to seek their own food than it is now when they are comfortably lodged and more care devoted to their feeding. Others have attributed it to some pernicious qualities in the

water which the animals drink, or in the food which is given to them; and with both these parties we are inclined to agree, and to attribute this disease in a great measure to vitiation of the blood.

The wild boar appears to be exempt from it; nor is leprosy known in America, Russia, or Spain, if we may believe the testimony of various authors and travellers.

Some have asserted it to be hereditary; but there are numerous facts on record in which some of the progeny of a perfectly healthy boar and sow have proved leprous, while a diseased sow has produced sound and healthy young.

Another question has likewise been much discussed, namely, the propriety or safety of eating the flesh of pigs that have died of this disease. These animals, however good condition they may appear to be in, are rather bloated than fat; the flesh is soft, and flabby, and tasteless, and will not keep; the bacon pale in colour and wanting consistency. Soup made with such flesh is white, greasy, and insipid, and has been known to produce vomiting and diarrhœa. We are not aware that there are any records of disease or other evil resulting from the eating of the flesh of leprous pigs; nevertheless it stands to reason that it cannot be wholesome and should not be made use of, for although no immediate ill effects may follow the eating of it, we cannot tell what insidious evils such vitiated and diseased food may engender in the human frame.

MANGE.

This cutaneous affection, which was formerly attributed to want of cleanliness or to some peculiar state of the blood, is now generally admitted to arise from the presence of certain minute insects termed *acari*. It is identical with the *scab* in sheep and the *itch* in the human being, which also were supposed to arise from corruption of the blood or acrid humour subsisting in it, or from filthiness, but which arise from this scabious insect. As far back as the twelfth century these *acari scabiei* were described by an Arabian physician; subsequently they were noticed and described by several German and Italian writers, and in 1812 and 1814 Herr Walz, a German veterinarian, and M. Gohier, an eminent French veterinary surgeon, found these insects in, and gave drawings of, and described those peculiar to, almost all our domesticated animals.

There is a very interesting translation from a pamphlet by Dr. Hertwig, given in the "Veterinarian" for 1838, in which a detailed account of the habits and history of these insects will be found.

The hog does not appear to suffer so much from mange or scab as the horse, sheep, and dog; in swine the pustules are usually chiefly developed under the arm-pits and on the interior of the thighs. They at first consist simply of red spots, vesicles, or pimples; but these gradually become connected together by minute burrows, or furrows existing beneath the skin, and eventually unite in the form of large scabs, which the animal, irritated by the itching, rubs into large blotchy sores.

Where the mange is recent, a tolerably strong decoction of tobacco or digitalis will often prove an efficacious wash for the diseased parts, or a solution of corrosive sublimate; but if the eruption is of long

standing and has degenerated into scabs, a solution of arsenic in the proportion of one ounce to a gallon of water, or, what is still better, sulphur and mercurial ointment in the proportion of an ounce of the former to a drachm of the latter, carefully and thoroughly rubbed into the skin, must be resorted to. A decoction of soot has also been recently discovered by an eminent French physician to be exceedingly efficacious in cases of cutaneous disorders. Two handfuls of soot are boiled during half an hour in a pint of water, the fluid is then strained off, and the lotion when cold used two or three times in the day. Creosote has also been used with success in the treatment of cutaneous eruptions. If the animal is in high condition, blood should be taken, and two or three doses of cooling physic given, or sulphur mingled with the food. Strict attention must be paid to cleanliness, and the animal kept apart from the rest of the herd. Mange is both hereditary and infectious. There are numerous instances of its having been communicated from one animal to another of a different species, and even to the human being.

In Austria, if mange appears in the hog within eight days after the sale it is presumed to have existed at the time of the said sale, and the animal is returnable to the vendor; and when it can be proved that he was aware of the unsoundness he not only has to return the purchase-money, but also to indemnify the purchaser for any loss or inconvenience he may have sustained, besides paying a fine equal to one-tenth of the value of the animal.

That the actual disease, namely, the scab and the irritation, arises from the presence and proceedings of the *acari*, there can be no shadow of doubt; but the question is, whence do these *acari* arise? Are they the product of some morbid state of the skin arising from constitutional derangement, or created by miasma or affluvia? We find mange in animals that are fed on too stimulating food, we also find it in others that are neglected and badly fed. How can these contradictions be reconciled? Here is a vast field for scientific research and experiment. As every grain of earth, and every drop of water, and every particle of air, is peopled with living beings, developed by certain causes, it is by no means an improbable theory to suppose that the germs of the *acari* may exist in a dormant state in the skin, and only be called into actual life by some of the vitiating influences which neglect or mismanagement produces, and once existing they follow the law of every created being, and propagate and multiply, and pass from one animal to another either by actual contact or by the intermediation of some other substance which both had touched. We admit, however, that this is mere theory, and call upon our professional brethren to aid us by their researches in our endeavours to discover the actual truth.

MEASLES.

This is rather a sub-cutaneous than an actual disease of the skin, consisting in a multitude of small watery pustules developed between the fat and the skin, and indeed scattered throughout the cellular tissue and adipose matter. It has, by many, been regarded as a milder form of leprosy; and so far as our present limited knowledge will allow us to judge, this supposition appears by no means an erroneous one.

The external appearances attending it are the development of reddish patches, somewhat raised above the surface of the skin, on the groin, the arm-pits, and the inside of the thighs at first, and subsequently on other parts of the body. The attendant symptoms are acceleration of the pulse, heat of the skin, cough, discharge from the nostrils, loss of appetite, nausea, swelling of the eyelids, feebleness of the hinder extremities, and the formation of blackish pustules under the tongue: eventually the skin usually comes off in patches.

The measles in swine is seldom fatal, and will gradually yield to the simplest cooling treatment, or even to mere attention to diet, temperature, and ventilation. Didymus tells us that Democrates prescribed bruised asphodile roots to be mingled with the food given to hogs, as an excellent remedy for this disease.* It sadly injures the quality of the meat, rendering it insipid, flabby, pale, and indisposed to take the salt. We should say that the flesh of measly pigs is positively unwholesome, although perhaps there are no cases on record in which it is proved that bad effects have resulted from the use of it.

The following was a remedy for this disorder used by the ancients:—“A hog having measles must be put into a sty and kept there three days and nights without food. Then take five or six apples, pick out the cores and fill up the holes thus made with flour of brimstone; stop up the holes and cast in the apples to the measly hog. Give him first one or two, then one or two more, and then, as being hungry he will eat them, give him all. Let him have nothing more to eat until the next day, and then serve him so again. Thus use him for five or six days, and he will become as well and as wholesome as ever.” In our opinion it is one very likely to be beneficial.

In Bavaria, Wurtemberg, and Baden, there is a warranty of four weeks and three days given against measles and other cutaneous eruptions in swine.

It yet remains to be discovered whether measles in swine is an epidemic, like that disorder in the human being, or whether it is hereditary, or whether, as many suppose, it arises from the development and presence of a variety of the *cysticercus*.

DESQUAMATION OF THE SKIN.

The following singular case, communicated to “The Veterinarian” by Mr. J. Sherwood, of Sittingbourn, appears to us not unworthy of record here.

“A few weeks ago the skin became hard on either side about nine or ten inches from the spine, and afterwards kept gradually separating towards the centre of the spine from the shoulder to the insertion of the tail. The bailiff cut off portions from time to time of the weight of nearly 10 lbs. in order to make the load with which the animal was encumbered the lighter, until the last week, when the hog lay down, and after taking his rest with his brethren (for he fed and looked as well as the rest, with the exception of the load on his back) he got up and left the substance behind him. It consisted of the entire skin so far as it had sloughed, with about two inches of adeps adhering to it

* Didymus, fol. 470.

in the middle, getting gradually thinner towards the sides, and weighing 20 lbs., which, added to the portions before removed, made a total of 30 lbs. The hog is now computed to weigh twenty score. He had not any medicine administered, as he did well the whole of the time."

CHAPTER X.

Operations—Bleeding—Castration—Catching and Holding—Drenching—Ringing.

BLEEDING.

THIS is a most useful and necessary operation, and one which in many diseases is of vital importance. The common and vulgar mode of getting blood from the pig is by cutting off portions of the ears or tail; but these modes of proceeding should only be had recourse to when local and instant blood-letting is requisite. The jugular veins of swine lie too deep and are too much imbedded in fat to admit of their being raised by any ligature about the neck; it is therefore useless to attempt to puncture them—we should only be striking at random. Those veins, however, which run over the interior surface of the ear, and especially towards its outer edge, may be opened without much difficulty: if the ear is turned back on to the poll, one or more of them may easily be made sufficiently prominent to admit of its being punctured by pressing the fingers on the base of the ear near to the conch; when the necessary quantity of blood has been obtained, the finger may be raised and it will cease to flow.

The palate veins which run on either side of the roof of the mouth are also easily opened by making two incisions, one on each side of the palate, about half way between the centre of the roof of the mouth and the teeth. The flow of blood may be readily stopped by means of a pledget of tow and a string, as in the horse.

M. Gohier, who had considerable practice in bleeding swine, was of opinion that the cephalic and sphenoid veins might be opened without any great exertion of skill by any one who possessed a little knowledge of anatomy. The lancet should be used somewhat obliquely, and a sufficient quantity of blood having been obtained, the flow arrested in the usual manner.

Mr. Cupiss recommends the brachial vein of the fore-leg (commonly called by farriers the *plate-vein*) as a favourable place for bleeding. This vein runs along the inner side of the fore-leg under the skin, and the best place for puncturing it is about an inch above the knee, and scarcely half an inch backwards from the *radius*. No danger need be apprehended from cutting two or three times if sufficient blood cannot be obtained at once. The vein will become easily discernible if a ligature is tied firmly round the leg just below the shoulder.

Columello tells us "to let blood from the ear," or "strike a vein beneath the tail at the distance of two inches from the buttocks, where it attains sufficient size for the purpose, and it must first be beaten with the sprig of a vine; then, when swelled up by the stroke of this rod, opened with a lancet, and, after enough blood has been drawn, the vein must be bound up with the rind of the willow or elm-tree."

This operation should always be performed with the lancet if possible: in cases of urgent haste, when no lancet is at hand, a small penknife may be used; but the fleam is a dangerous and objectionable instrument.

CASTRATION OR SPAYING.

This operation is performed on many of our domesticated animals, with the view of increasing their docility and usefulness, and on others to dispose them to fatten and attain to earlier maturity; it consists in removing the testicles of the male, and the ovaries, and sometimes a more or less considerable portion of the uterus, of the female.

Pigs are chiefly castrated with a view to fattening them, for it is generally asserted that a sow that has not been spayed will never gain flesh:—

“The plaguy pigs are never worth their meat.
They neither feed nor are they fit to eat”—

when left in a state of nature, says an old north-country rhyme; and doubtless castration has the required effect, and therefore is less objectionable when performed on the pig, than when the horse or dog is subjected to it; for at the same time that it increases the quiescent qualities of the animal, it diminishes his courage, spirit, and nobler attributes, and even affects his form. The tusks of a castrated boar never grow like those of the natural animal, but always have a dwarfed, stunted appearance.

If possible, this operation should be performed in the spring or autumn, as the temperature is then more equable, and care should be taken that the animal is in perfect health. Those which are fat and plethoric should be prepared by bleeding, cooling diet, and quiet. Pigs are castrated at all ages, from a fortnight to three, six, and eight weeks, and even four months old. There are various modes of performing the operation: we will begin by quoting those described by Professor Vatel:—*

“*Castration by simple division of the spermatic cord.*—If the pig is not more than six weeks old, an incision is made at the bottom of the scrotum, the testicle pushed out, and the cord cut without any precautionary means whatever. But when the animal is older, there is reason to fear that hemorrhage to a greater or less extent will supervene; consequently it will be advisable to pass a ligature round the cord a little above the spot where the division is intended to take place.

“*Castration by tearing the cord.*—Swine are thus operated on by some cutters:—An assistant holds the pig, pressing the back of the animal against his chest and belly, keeping the head elevated, and grasping all the four legs together; or, which is the preferable way, one assistant holds the animal against his chest, while another kneels down and secures the four legs. The operator then grasps the scrotum with his left hand, makes one horizontal incision across the base of it, opening both divisions of the bag at the same time. Then laying down his knife, he presses the testicles out with his finger and thumb, grasps them between his teeth and tears them out. He then closes the wound by pressing the edges gently together with his fingers; the tearing prevents all hemorrhage, and the wound speedily heals. This mode

of operation is sometimes performed on animals two and three years old. Some break the spermatic cord without tearing it: they twist it, and then pull it gently and firmly until it gives way.

"Castration by sawing or scraping."—Here a portion of the base of the scrotum is cut off, the testicles forced out, and the cord sawn through by a somewhat serrated but blunt instrument. The hemorrhage, if any there be, is arrested by introducing ashes into the wound. The animal is then dismissed, and nothing further done with him. Fromage de Feagre has castrated many pigs of three or four months old by dividing the spermatic cord in this way. This mode of operating, however, should only be practised on very young animals.

"Castration by ligature."—Here a waxed cord is passed as tightly as possible round the scrotum above the epididymes, which completely stops the circulation, and in a few days the scrotum and testicles will drop off. This mode of operating should never be performed on pigs more than six weeks old, and the spermatic cord should always be first of all uncovered."

We cannot approve of the tearing or gnawing the testicle with the teeth; it is a disgusting practice, and inflicts unnecessary pain on the patient: the use of a blunt knife is far preferable, as this lacerates the part equally as much without so bruising it and rendering it painful; and it is the laceration only we require, in order to prevent the subsequent hemorrhage which would occur if the cord were simply severed with a sharp instrument.

The castration by ligature requires great nicety and skill, otherwise accidents will occur, and considerable pain and inflammation be caused. Too thick a cord, a knot not tied sufficiently tight, or a portion of the testicle included in the ligature, will prevent the success of the operation.

The most fatal consequence of castration is tetanus, induced by the shock communicated to the nervous system by the torture of the operation.

In spaying the sow the animal is laid upon its left side and firmly held by one or two assistants; an incision is then made into the flank, the fore-finger of the right hand introduced into it, and gently turned about until it encounters and hooks hold of the right ovary, which it draws through the opening; a ligature is then passed round this one, and the left ovary felt for in like manner. The operator then severs off these two ovaries, either by cutting or tearing, and returns the womb and its appurtenances to their proper position. This being done, he closes up the womb with two or three stitches, sometimes rubs a little oil over it, and releases his patient, and all generally goes on well; for the healing power of the pig is very great, as the following fact will testify:—

Mr. Thomson, veterinary surgeon at Beith, N. B., was castrating a pig, and while cutting through the peritoneum one of the assistants lost his hold, and the animal sprang up. The scalpel was plunged deep into the belly, entered one of the convolutions of the ileum, and divided one of the guts almost through, besides making a wound in the mesentery. Mr. Thomson sewed up the mesentery with a fine needle and thread and restored it to its place, and secured the side with firm stitches—not, however, with much hope of seeing his patient recover.

But, to his surprise, two days afterwards little appeared to be the matter, and in a short time the animal was well.*

The after treatment is very simple. The animals should be well littered with clean litter, in sties weather-tight and thoroughly ventilated; their diet should be attended to; sour milk or whey, with barley-meal, is an excellent thing to give at these times; it is well to confine them for a few days, as they should be prevented from getting into cold water or mud until the wound is perfectly healed, and also from creeping through hedges or fences.

The best age for spaying a sow is about six weeks; indeed, as a general axiom, the younger the animal is castrated the better it gets over the operation, which is seldom attended by fatal results. Some persons, however, have two or three litters from their sows before they operate upon them; where this is the case the consequences are more to be feared, as the parts have become more susceptible, and are consequently more liable to take an inflammation. Lisle says:—"Where this is done, it is best to spay a sow two or three days before her litter of pigs are weaned, because then, if harm follows the operation, the young ones will draw off the venom."†

The following extraordinary expertness at pig-spaying is worthy of mention:—Mr. J. Bowman, V. S. at Howden, undertook for a wager to spay one hundred sows and pigs in two hundred minutes. That number being procured, and umpires chosen from among the neighbouring practitioners, Mr. B. commenced at ten o'clock in the morning at the Wellington Inn.

The first eleven were disposed of in twelve minutes; the next five-and-forty in fifty-nine minutes and thirty seconds; and the remaining four-and-forty in seventy-nine minutes and fifty seconds; thus completing the task in two hours, thirty-one minutes, and twenty seconds, being forty minutes and forty seconds within the given time, and averaging a minute and a-half for each one.

The ninety-third occupied only fifty-six seconds. The task would have been completed in even less time, but the forty-fifth pig, from some malformation of the ovaria which made it difficult to extract it, took six minutes to operate on.‡

CATCHING AND HOLDING THE PIG.

Swine are very difficult animals to obtain any mastery over, or to operate on or examine. Seldom tame or easily handled, they are at such periods most unmanageable, kicking, screaming, and even biting fiercely. Hurtrel d'Arboval recommends the following means of getting hold of them:—"Fasten a double cord to the end of a stick, and beneath the stick let there be a running noose in this cord; tie a piece of bread to the cord and present it to the animal, and when he opens his mouth to seize the bait, catch the upper jaw in the noose, run it tight, and the animal is fast."§

Another means is to catch one foot in a running noose suspended from some place, so as to draw the imprisoned foot off the ground; or to envelope the head of the animal in a cloth or sack.

* The Veterinarian for 1844. † Lisle's Husbandry. ‡ The Veterinarian for 1838. § Dictionnaire de Médecine et de Chirurgie Vétérinaire, vol. i.

But, so far as it can be, all coercion should be avoided, for the pig is naturally so averse to being handled, that in his struggles he will often do himself far more mischief than the disease we seek to investigate or remedy would effect.

DRENCHING.

Here again the observations with which we closed the preceding paragraph are applicable, for there are more instances than one on record in which the pig has, in his struggles, ruptured some vessel and died on the spot, or so injured himself as to bring on inflammation and subsequent death. Whenever it is possible, the medicine should be mingled with a portion of food, and the animal thus cheated or coaxed into taking it. Where this cannot be done, the following is the best method:—

Let a man get the head of the animal firmly between his knees, without, however, pinching it, while another secures the hinder parts. Then let the first take hold of the pig's head from below, raise it a little, and incline it slightly towards the right, at the same time separating the lips on the left side so as to form a hole into which the fluid may be gradually poured, not more being introduced into the mouth at a time than can be swallowed at once. Should the beast snort or choke, the head must be released for a few moments, or he will be in danger of being strangled.

RINGING.

The operation of ringing is performed in order to counteract the propensity swine have to dig and furrow up the earth. The operator is usually the village farrier or blacksmith—

“ And pigs he rung, and bells he hung,
And horses shod and cured.”

The ring is passed through what appears to be a prolongation of the septum, between the supplemental, or snout-bone, and the proper nasal. The animal is thus unable to obtain sufficient purchase to use his snout with any effect without causing the ring to press so painfully upon the part that he is speedily compelled to desist. But the ring is apt to break, or it wears out in process of time and has to be replaced. The operation is most painful, and the shrill squeaks of the animal undergoing it cause it to be a perfect nuisance to the neighbourhood.

John Lawrence gives the following directions concerning this operation: “The snouts of pigs should be perforated at weaning-time, after they shall have recovered from castration; and it will be necessary to renew the operation as they become of large growth. It is too generally neglected at first; but no pigs, young or old, should be suffered to roam at large unringed. It should be ascertained that the sow's rings are sufficiently strong previously to her taking the hog, on account of the risk of abortion from the operation being renewed while she is in pig. Care must be taken by the operator that he go not too close to the bone, and that the ring turns easily.”

The far better mode of proceeding is, when the pig is young, to cut through the cartilaginous and ligamentous prolongations by which the

supplementary bone is united to the proper nasals. The divided edges of the cartilage will never unite again, and the snout always remain powerless.

CHAPTER XI.

Breeding: Principles of—Choice of the Boar and Sow—Best Breeds—Age at which the Sow may be used for Breeding—Proper Age for the Boar to commence at—Period of Gestation—Fruitfulness of Sows—Treatment of them during Pregnancy—Abortion—Parturition—Cæsarian Operation—Monstrosities—Treatment of the Sows while Nursing—Treatment of the Young while Sucking—Weaning and after Treatment—Prolific power of Swine.

We now approach one of the most difficult and important divisions of our subject—breeding.

The object of the farmer or breeder is to produce and retain such an animal as will be best adapted to the purpose he has in view, be that the consumption of certain matters which could not be otherwise so well disposed of; the converting into hams, bacon, and pork; or the raising of sucking-pigs and porkers for the market. Almost all farmers, nay, we might almost say, every cottager who has a bit of ground, keep one or more pigs to devour the offal and refuse which would otherwise be wasted; and the farmer finds a sufficiency for their keep, while the cottager begs wash and other matters, or turns the beast out into the lanes to forage for himself. But this is a matter totally distinct from “breeding swine.” In the former case the animal or animals are purchased young, for a small price (each person buying as many as he considers he shall have food enough for,) and then sold to the butcher when in proper condition to be killed; and thus a certain degree of profit is realised. In the latter many contingencies must be taken into calculation, viz. the available means of feeding them; whether or not that food might be more profitably disposed of; the facilities afforded by railways, by the vicinity of towns, or large markets, &c. for disposing of them. And the rapid growth of railways is now affording these facilities to all parts of the United Kingdom. Formerly the inhabitants of remote localities had no means of conveying their swine to a favourable market except the tedious one of driving them, or the expensive one of conveying them in carts.

Agricultural writers seem to be very much divided in their opinions as to the relative advantages of breeding or buying, but all allow that the keeping of swine is one of the most profitable parts of the business of a farm. Whoever determines upon breeding must make up his mind in the first place what is the shape and what the qualities he wishes to obtain, and then steadily bear this in mind as he pursues his object; not with wavering caprice, now selecting a cross of one sort, now one of another, but adhering to a system well laid down, and then he will find his efforts attended with success. The great *desideratum* in almost all establishments is an animal that will grow rapidly, and attain to the earliest maturity and greatest weight in the shortest period, and on the smallest and most economical amount of food.

It is a generally admitted fact in the principles of breeding that the offspring usually inherit the bodily and constitutional qualities of one

or both parents; and in swine it is the boar whose qualities chiefly predominate in the offspring; hence it will be necessary most carefully to select the male animal. Thäer, in his admirable work, says—

CHOICE OF THE BOAR AND SOW.

“In the breeding of swine, as much as in that of any other live stock, it is important to pay great attention not only to the breed, but also to the choice of individuals. The sow should produce a great number of young ones, and she must be well fed to enable her to support them. Some sows bring forth ten, twelve or even fifteen pigs at a birth, but eight or nine is the usual number, and sows which produce fewer than this must be rejected. It is, however, probable that fecundity depends also on the boar; he should therefore be chosen from a race which multiplies quickly.

“Good one-year bacon-hogs being much in request, we must do all we can to obtain a breed well adapted for producing them. Swine of such a breed may be known by their long bodies, low bellies, and short legs. Long pendulous ears are usually coupled with these qualities and attract purchasers. If, however, as is often advisable in large dairies and cheese factories, hogs are to be sold at all seasons to the butchers, great attention must be paid to quickness of growth and facility of gaining flesh, so that the animals may attain their full growth and be ready for killing before they are a year old. This quality is particularly prominent in the Chinese and African breeds; but among our ordinary varieties, hogs are often met with which are better adapted for this purpose than for producing large quantities of bacon and lard.

“The boar should be selected from a breed well suited to these several purposes; he must be sound and free from hereditary blemishes; he should be kept separate from the sows till he is about a year old, and has finished his growth or he will begin to leap too early. He is usually castrated before completing his third year, otherwise his flesh becomes uneatable. If, however, he is of a peculiarly excellent breed, one which cannot be easily replaced, his flesh may be sacrificed for the sake of preserving him for breeding from a few years longer.

“A boar left on the pasture at liberty, with the sows, might suffice for thirty or forty of them; but as he is usually shut up, and allowed to leap at stated times only, so that the young ones may be born nearly at the same time, it is usual to keep one boar for ten or twelve sows. Full grown boars being often savage, and difficult to tame, and attacking men and animals, must be deprived of their tusks.

“The sow must be chosen from a breed of proper size and shape, sound and free from blemishes and defects. She should have at least twelve teats; for it is observed that each pig selects a teat for himself and keeps to it, so that a pig not having one belonging to him would be starved. A good sow should produce a great number of pigs, all of equal vigour. She must be very careful of them, and not crush them by her weight; above all, she must not be addicted to eating the after-birth, and what may often follow, her own young ones. If a sow is tainted with these bad habits, or if she has difficult labours, or brings forth dead pigs, she must be castrated forthwith. It is therefore proper to bring up several young sows at once, so as to keep those only which

are free from defects. Breeding sows and boars should never be raised from defective animals."

According to Varro and Columella, the ancients considered the distinguishing marks of a good boar to be—a small head, short legs, a long body, large thighs and neck, and this latter part thickly covered with strong erect bristles.

Our most experienced breeders prefer an animal with a long cylindrical body, small bones, well-developed muscles, a wide chest—which denotes strength of constitution, a broad straight back, short head and fine snout, brilliant eyes, a short thick neck, broad well-developed shoulders, a loose mellow skin, fine bright long hair and few bristles, and small legs and hoofs. Some give the preference to long flapping ears; this is the case especially in several of our western counties, but experience seems to demonstrate that those animals are best which have short, fine erect ears. The boar should always be vigorous and masculine in appearance.

That quaint old writer Lisle, in his "Husbandrie," gives the following advice on this subject—advice more suited to swine "as they were" than to the improved breeds which are now so generally replacing the heavy old races, but still worthy of some degree of attention:—

"In all kinds of four-footed beasts, the shape and form of the male is chosen with great care, because the progeny is frequently more like the father than the mother; wherefore, in swine-cattle also, certain of them must be approved, which are choice and singular for the largeness of their whole body, and such as are rather square (than those that are long or round,) with a hanging-down belly, vast buttocks, but not so long legs and hoofs, of a large and glandulous neck, with short snouts, and turned upwards; and especially, which is more to the purpose, the males must be exceeding salacious and such as are proper for gendering from the age of one year till they come to their fourth year: nevertheless they can also impregnate the female when they are six months old. Sows of the longest size and make are approved, provided they be, in the rest of their members, like the boars which have been already described.

"If the country is cold, and liable to hoar-frost, the herd must be chosen of an exceeding hard, thick, and black bristle. If it be temperate, and lie exposed to the sun, the cattle that is smooth and has no bristles, or even that which is white, and proper for the mill and the bakehouse, may be fed."

But although the chief care must be bestowed on the selection of the male animal, we must not be led to imagine that the female may be chosen at random. One of good form and breed, free from constitutional defects, and from disease of any kind; not addicted to vice, and especially not to feeding on flesh or carrion, or destroying rabbits, or poultry, should be chosen. Also those which produce the finest and most numerous progeny should be kept for breeding, especially if at the same time they are good nurses; and the comparatively barren animals spayed and fattened. Sows that have very low bellies almost touching the ground, seldom produce large or fine litters. A good-sized sow is generally considered more likely to prove a good breeder and nurse, and to farrow more easily and safely, than a small delicate

animal. Few of our domesticated animals suffer so much from being bred in-and-in as swine. Where this system is pursued, the number of young ones is decreased at every litter, until the sows become, in a manner, barren. As soon as the slightest tendency to this degeneracy is observed, the breed should be crossed from time to time, keeping sight, however, while so doing, of the aim in view. The Chinese and Siamese pigs will generally be found to be the best which can be used for this purpose, as a single, and even two crosses, with one of these animals, will seldom do harm, but often effect considerable improvement. The best formed of the progeny resulting from this cross must be selected as breeders, and with them the old original stock crossed back again.

"Selection, with judicious and cautious admixture, is the true secret of forming and improving a breed," says an old and well-established axiom; and so it is. Repeated and indiscriminate crosses are as injurious as an obstinate adherence to one particular breed, and as much to be avoided; and of this most persons seem to be fully aware, for a systematic alteration is extending itself throughout all our English breeds of swine; the large, heavy, coarse breeds are almost extinct, and a smaller race of animals—more apt to fatten, less expensive to keep, attaining earlier to maturity, and furnishing a far more delicious and delicate meat—have taken their place.

It would be useless to point out certain breeds as being the most profitable or advantageous, so much depends upon the object for which the animals are raised; and besides, each breeder of any experience has in general his own pet stock breed, frequently one that has been "made," if we may be allowed the expression, by himself or his progenitors. This will be found to be the case in all great pig-breeding localities, and it frequently happens that the actual stock from which some of the present choicest races of swine sprang cannot be traced farther back than some ancestor or ancestress celebrated for the number of prizes he or she, or their immediate decendants, have won. At least we have found this to be the case in almost every instance in which we have endeavoured to arrive at a knowledge of the actual parent stock of some of the most perfect and valuable animals we have met with or heard of. The Berkshire, the Improved Essex, and the New Suffolk and Bedfordshire breeds may, however, with the Chinese and Napolitan, be instanced as the best stocks from which to raise a small-boned, thriving, profitable race, adapted for almost every purpose.

A sow is capable of conceiving at the age of from seven to ten months, but it is always better not to let her commence breeding too early, as it tends to weaken her when she does. From ten to twelve months old will be about the best age. Thäer says, "Sows are almost always in heat until they have received the boar; this state commences even as early as at the age of four or five months, but they are usually a year old before they are allowed to be put to the boar."

The boar should be at least a twelvemonth old before he is employed for the purpose of propagating his species, and during that time should have been well and regularly fed and exercised. One boar may be allowed to serve from six to ten sows, hut on no account more. The best plan is to shut up the boar and sow in a sty together; for when

turned in among several females, he is apt to "ride" them so often that he exhausts himself without effect.

The period of gestation averages from seventeen to twenty weeks, according to the age, constitution, &c., of the mother; young or weakly sows farrow earlier than those of more mature age or stronger constitutions. It is commonly asserted that three months, three weeks, and three days, is the period of gestation; but, from M. Tessier's observations on twenty-five sows, it appears that it varies from 109 to 123 days.

A good breeding sow will produce two if not three litters in a year, but two should be the outside number; for where she is suffered to have more, the pigs are not so fine or so many in number, nor can she suckle them so well. How many years they would continue to breed is scarcely known, as it is generally considered to be most advantageous to spay them in their second, or at any rate early in their third year, and then fatten them for the butcher, especially where there is always a stock of young sows to replace them; for after the just-mentioned period the litters are seldom so fine, and the animal herself deteriorates in value. Some breeders, indeed, only suffer a young sow to have one litter, and then immediately spay and fatten her, as the bacon is then supposed to be equally as good as that of an animal spayed in the very onset. This is mainly a question of choice or economy. An agricultural author of some repute states that "a sow is fit for pigging up to her seventh year, and many will continue to be so even longer. The more prolific, however, the animal is, the sooner does she grow old and her fruitfulness decay."

But they doubtless would go on farrowing for many years, for there are instances on record of sows that have produced as many as eight or ten pigs at a litter when in their eighth and tenth years. Selbourne, in his "Natural History," gives an account of a half-bred bantam sow, kept by a friend of his, more from curiosity than with any view to profit, "who was as thick as she was long, and whose belly swept on the ground, till she was advanced to her seventeenth year; at which period she showed some tokens of age by the decay of her teeth and the decline of her fertility.

"For about ten years this prolific mother produced two litters in the year, of about ten at a time, and once above twenty at a litter; but, as there were near double the number of pigs to that of teats, many died. From long experience in the world, this female was grown very sagacious and artful. When she found occasion to converse with a boar, she used to open all the intervening gates, and march, by herself, up to a distant farm where one was kept, and, when her purpose was served, would return by the same means. At the age of about fifteen, her litters began to be reduced to four or five; and such a litter she exhibited when in her fatting-pen. She proved, when fat, good bacon, juicy and tender; the rind or sward was remarkably thin. At a moderate computation she was allowed to have been the fruitful parent of three hundred pigs—a prodigious instance of fecundity in so large a quadruped. She was killed in the spring of 1775."

Although we should by no means advise the keeping of an animal to such an age, still, notwithstanding that it is the fashion or custom to do otherwise, we would advise every breeder never to part with a sow while she continues to bring forth a numerous and fine progeny, which

many will do for years, and to be a good nurse; and in general these animals become better nurses the oftener they farrow: her value he knows; the value of the young animal that he intends should succeed her, has yet to be tested; and if one of the two must be fattened for the butcher, we should decidedly recommend that it were the untried one. Varro states that we may judge of the fruitfulness of a sow from her first litter, the subsequent ones being generally all of about the same number.

A sow that brings forth less than eight pigs at a birth the third or fourth time she farrows is worth little as a breeder, the sooner she is fattened the better; but a young sow that produces a great number at her first farrowing cannot be too highly valued.

Whenever it is practicable, it should always be so arranged that the animals shall farrow early in the spring, and at the latter end of the summer or quite the beginning of the autumn. In the former case the young pigs will have the run of the early pastures, which will be a benefit to them and a saving to their owners; and there will also be more whey, milk, and other dairy produce which can be spared for them by the time they are ready to be weaned. And in the second case there will be sufficient time for the young to have grown and acquired strength before the cold weather comes on, which is always very injurious to sucking pigs.

TREATMENT OF SOWS DURING PREGNANCY.

Sows with pig should be well and judiciously fed; that is to say, they should have a sufficiency of wholesome nutritious food to maintain their strength and keep them in good condition, but should by no means be allowed to get fat, as when they are in high condition the dangers of parturition are enhanced, the animal is more awkward and liable to smother or crush her young, and besides, never has as much or as good milk as a leaner sow. She should also have a separate sty: for swine are prone to lie so close together, that if she were amongst others her young would be in great danger; and this sty should be perfectly clean and comfortably littered, but not so thickly as to admit of the young being able to bury themselves in the straw.

As the time of her farrowing approaches she should be well supplied with food, especially if she be a young sow, and this is her first litter, and also carefully watched in order to prevent her from devouring the after-birth, and thus engendering a morbid appetite which will next lead her to fall upon her own young. A sow that has once done this is never afterwards to be depended upon. Hunger, thirst, or irritation of any kind, will often induce this unnatural conduct; and this is another reason why a sow about to farrow should have a sty to herself, and be carefully attended to, and have all her wants supplied.

ABORTION.

This accident is by no means of so common occurrence in the sow as in many of our other domesticated animals. There are various causes which will tend to produce it; insufficiency of food, eating too much succulent vegetable food, or unwholesome unsubstantial diet; blows and falls will also induce it; and one very prevalent cause arises from this animal's habit of rubbing itself against hard bodies in order to allay

the irritation produced by the vermin or cutaneous eruptions to which swine are subject.

Reiterated copulation does not appear to produce abortion in the sow, at least to the extent it does in other animals.

The symptoms indicative of approaching abortion are similar to those of parturition, only more intense. There is generally restlessness, irritation, and shiverings; and the cries of the animal testify the presence of severe labour-pains. Sometimes the rectum, vagina, or uterus becomes relaxed, and one or the other protrudes, and often becomes inverted at the moment of the expulsion of the fœtus, preceded by the placenta, which presents itself foremost.

Nothing can be done to prevent abortion at the last hour; all that we can do is, from the first to remove every predisposing cause.

The treatment will depend upon circumstances. Where the animal is young, vigorous, and in high condition, bleeding will be beneficial, not a copious blood-letting, but small quantities taken at different times; purgatives may also be administered. If, when abortion has taken place, the whole of the litter are not born, emollient injections may be resorted to with considerable benefit; otherwise the after-treatment should be much the same as in parturition, and the animal should be kept warm and quiet and clean, and allowed a certain degree of liberty.

Whenever one sow has aborted, the breeder should immediately look about for the causes likely to have induced this accident, and endeavour, by removing them, to secure the rest of the inhabitants of his piggery from a similar fate.

In cases of abortion the fœtus is seldom born alive, and often has been dead for some days; where this is the case—and whether it is so or not will be easily detected by a peculiarly unpleasant putrid exhalation and the discharge of a fetid liquid from the vagina—the parts should be washed with a diluted solution of chloride of lime, in the proportions of one part chloride to three parts water, and a portion of this lotion may be gently injected into the uterus if the animal will submit to the doing so. Mild doses of Epsom salts, tincture of gentian, and ginger will also act beneficially in such cases, and with attention to diet, soon restore the animal.

PARTURITION.

The approach of the period of farrowing is marked by the immense size of the belly, by a depression of the back, and by the distention of the teats. The animal gives evident symptoms of acute suffering, and wanders restlessly about, collecting straw and carrying it to her sty, grunting piteously the while.

As soon as this is observed, she should be enticed into a separate sty and carefully watched. On no account should several sows be permitted to farrow in the same place, as they will inevitably irritate each other, and devour their own or one another's young.

The young ones should be taken away as soon as they are born, and deposited in a warm spot, for the sow being a clumsy animal, is not unlikely in her struggles to overlay them; nor should they be returned to her until all is over, and the afterbirth has been removed, which

should always be done the moment it passes from her; for, young sows especially, will invariably devour the afterbirth if permitted, and then, the young being wet with a similar fluid and smelling the same, will eat them one after another. Some persons advise washing the backs of the young pigs with a decoction of aloes, colocynth, or some other nauseous substance, as a remedy for this; but the simplest and easiest one is to remove the little ones until all is over and the mother begins to recover herself and seek about for them, on which they should be put near her.

It has been frequently observed that each little pig has its own peculiar teat, and will not willingly suck from any other; therefore, as the front teats yield most milk, the smallest pigs should be placed to them. If more young are farrowed than the mother has teats, the most weakly-looking must be destroyed, unless it should so happen that there is another sow at hand which has fewer pigs than teats, in which case they may be put to her, if this can be done without her knowledge; though some writers affirm that a sow will give her teats indifferently to her own offspring or to that of a stranger.

It does not, however, always happen that the parturition is effected with such ease. Cases of false presentation, of enlarged fœtus, of debility in the mother, often render it difficult and dangerous. The womb will occasionally become protruded and inverted in consequence of the forcing pains of difficult parturition, and even the bladder has been known to come away. These parts must be returned as soon as may be; and if the womb has come in contact with the dung or litter and acquired any dirt, it must be first washed in luke-warm water, and then returned and confined in its place by means of a suture passed through the lips of the orifice. Some foreign veterinarians place a pessary high up the vagina, and secure it in its situation by means of an iron ring or wire; but this is a complicated operation, and could not be performed without great difficulty on so obstinate an animal. The easiest and perhaps the best way is not to return the protruded parts at all, but merely tie a ligature around them and leave them to slough off which they will do in the course of a few days, without effusion of blood or further injury to the animal. No sow that has once suffered from protrusion of the womb should be allowed to breed again.

Mr. Ramsden, of Rippon, gives the following account of a case of difficult parturition:—

"About the middle of August, 1840, I was called in and requested to assist a sow that was in labour, could not rise, and seemed to be in great suffering. I relieved her of one, gave her some gruel, and hoped that she would be able to effect the parturition of the remaining ones without aid.

"On my return she was perfectly senseless. The young pig was endeavouring to suck. The parturition had not in the least degree advanced. I pressed with my left hand over the diaphragm, which recalled in a slight degree the pains, and empounded my right hand gradually. I then drew out a second pig; it lay about four inches anterior to the pelvis. The stupor of the mother was a little removed, and at length I got the whole litter of ten pigs, and also the placental membrane. This was the first case of the kind that ever came under my notice."*

* The Veterinarian, vol. xiv.

Another and still more interesting case is given by Mr. Cartwright, veterinary surgeon:—

“On the 11th of July, 1839, I was requested to attend a sow, the property of a farmer near this town. The poor animal had been in labour six days. During the last three days she was not able to stand, nor had she taken any food, and her death was expected every hour. She was a very fat animal, and the owner informed me that she was about ten days past her time of pigging, and that he was confident the pigs were dead. I was of the same opinion; and, after a minute examination, felt confident that nothing short of the Cæsarean operation could save her; at the same time informing the owner that she might die in consequence of, or during, the operation.

“The operation was consented to; and I proceeded first to secure her legs, and to have them firmly extended their full length, and retained there by assistants. I next placed a bundle of straw underneath her, which gave the belly a round and prominent position, rendering it more tense and firm, and at the same time giving me considerable advantage in operating.

“My first proceeding was to clear away the hair in the direction of my intended incision, in which I, at the onset, had made up my mind to follow the theory taught in operative surgery, viz. always to make the incisions in the same direction as the muscular fibres, and, above all, never to sever a muscle if it could be avoided. The hair being removed, I was about to make the incisions lengthways, in the course of the *linea alba*, when it suddenly occurred to me that I should not, in this case, be able to keep the lips of the wound approximated by sutures or bandages, on account of the depending state of the abdomen and its contents. I therefore determined to make the incisions more on the side, and across the *oblique externus abdominis*. I accordingly cut freely through the integuments for about eight inches in length, which I accomplished with a common scalpel. Next I penetrated through the adipose or fatty matter underneath, of which there was no lack; and then cut down on the muscle, at the superior part of the incision, quite through, and exposing the peritoneum. I now introduced my forefingers as directors, and with the curved bistoury laid the abdomen freely open.

“The lips of the incision or wound of course receded from each other to a great distance, and a slight arterial hemorrhage ensued, which I thought proceeded from the circumflex artery of the ilium. If the incision had been made longitudinally, this might have been prevented; but as the hemorrhage soon ceased, it was of little consequence. The intestines were much inflated with gas, and protruded as far as the wound of the peritoneum extended.

“I now introduced my right hand, and distinctly felt the situation of the uterus, when the animal made a desperate struggle, and some of the small intestines escaped. I found it necessary for an assistant to introduce his hand, to prevent a repetition of this. The bladder was distended with urine, which proved somewhat troublesome, and I had no catheter at hand. I was now about to make a second attempt to open the uterus, when I accidentally felt the pulsation of a large artery. Had I divided the uterus in the same direction as the incision in the abdomen I should have cut the artery. Was it the uterine or va-

ginal artery? I placed my hand inferior to the vessel, and felt a young one. Next, with a scalpel in my right hand, guarded at the point with my forefinger, fearing that the sow might struggle and the instrument wound some of the intestines, I cut through the uterus, introduced my finger guarding the scalpel, and effected an opening into it about six inches in length. I then introduced my hand, laid hold of one of the foetal pigs, and drew it out. In this way I proceeded until I removed the whole number, which amounted to seven.

"The operation being thus far completed, her legs were drawn towards each other, which brought the lips of the wound into approximation, and I retained them there by strong adhesive plasters, over which I placed a roller passing three times round her body. I now proceeded to examine my patient: she was, as might be expected, in a very weak state; and when her head was raised, it fell again upon my hand as if she was dead. As she lay in this exhausted state, not a muscle except the involuntary ones moving, I gave her a little brandy and water, and then closed the door and left her. The general opinion of the by-standers was, that in a few minutes she would be dead: this was about 4 P. M. Indispensable business prevented me from seeing her until ten o'clock, when I was glad to find my patient somewhat revived. I gave more brandy and beef-tea, and left her for the night.

"At 6 A.M. there was a decided improvement; the extremities were warm, the respiration tranquil, with an occasional grunt and pricking or moving of the ears; some fæces had passed during the night. I doubted whether the bladder had been emptied, and therefore introduced a small catheter which I use for sheep, &c., and took away a great quantity of water. I ordered more weak brandy and water and broth.

"At 6 P.M. the symptoms were improving, excepting that the side surrounding the incision was a little swelled; I therefore ordered fomentations to be applied, using hot cloths, with but little water.

"18th.—Doing well; the secretions regular; and she for the first time voluntarily took a little milk, with a drachm of brandy, of which she appeared fond. From this time she continued to improve daily; and on the fifth day from the operation she was able to stand, and fed well. The roller round her body was not removed for a month, and the plaster remained for nearly three months. When it came away the wound was beautifully healed. This animal has attracted considerable attention in the neighbourhood, and she is now as fat as she can be, and a fine specimen of the short-eared breed."*

MONSTROSITIES.

Monstrosities are often farrowed by swine. It would be difficult to assign any cause for this, did we admit, with most persons, that these are peculiarly stupid and unimaginative animals; but as in Chapter III. we have already declared our opinion to be a contrary one, the inexplicability of the matter is done away with.

Mr. Ellis, V. S., of Liverpool, gives an account of six sows belonging to one person which all produced blind young ones, the greater part of which were without the least semblance of an eye, the orbit

* The Veterinarian, vol. xiii.

being quite empty. Some of them had four ears each. Only four out of the whole lot lived; they were either brought forth dead or died immediately after birth.

One of the sows could not farrow any of her young ones, they being three times the proper size, and in a state of decomposition. The Cæsarean operation was therefore performed, as the only means of saving her; but it had been delayed too long; she only lived three hours after it.

These pigs were all got by one boar, but the sows were of different breeds.

TREATMENT OF THE SOWS WHILE SUCKLING.

More depends upon this than many persons seem to have the least idea of, both as regards the mother and the young; and many a fine sow and promising litter have been ruined for want of proper and judicious care at this period.

Immediately after farrowing many sows are apt to be feverish; where this is the case, a light and sparing diet only should be given them for the first day or two, as gruel, oatmeal-porridge, whey, and such-like. Others, again, are very much debilitated, and require strengthening; for them strong soup, bread steeped in wine or in a mixture of brandy and sweet spirits of nitre, administered in small quantities, will often prove highly beneficial.

Gradually the rations must be increased and given more frequently; and they must be composed of wholesome, nutritious, and succulent matters. All kinds of roots—carrots, turnips, potatoes, and beet-root—well steamed or boiled, may be given, but never raw; bran, barley and oatmeal, bean-flour, Indian corn, whey, sour, skim, and butter-milk, all are perfectly well adapted for this period; and, should the animal appear to require it, grain well bruised and macerated may also be added. Bean-flour is considered by many persons to create an abundance of milk; and there are many who deem barleymeal too stimulating, and advise that it should never be used alone, but always one-third oatmeal to two-thirds of the barleymeal. Whenever it is possible, the sow should be turned out for an hour each day to graze in a meadow or clover-field, as the fresh air and exercise and herbage will do her an infinity of good. The young pigs must be shut up for the first ten days or a fortnight, after which they will be old enough to follow her and take their share of the benefit.

The rations should be given regularly at certain hours; small and often-repeated meals are far preferable to large ones, for indigestion or any disarrangement of the functions of the stomach vitiates the milk, and produces diarrhœa and other similar affections in the young.

The mother should always be well but not over-fed; the better and more carefully she is fed, the more abundant and nutritious will her milk be, the better will the sucking-pigs thrive, and the less will she be pulled down by suckling them.

When a sow is weakly, and has not a sufficiency of milk, the young pigs must be taught to feed as early as possible. A kind of gruel, made with skim-milk and bran or oatmeal, will be the best thing for this purpose; or a soup composed of potatoes, boiled, and then mashed in milk or whey, with or without the addition of a little bran or oatmeal.

Towards the period when the pigs are to be weaned the sow must be less plentifully fed, otherwise the secretion of milk will be as great as ever; and it will accumulate, and there will be hardness, and perhaps inflammation, of the teats. Should it appear requisite, a dose of physic may be given to assist in carrying off the milk; but in general a little judicious management in the feeding and weaning will be all that is requisite.

TREATMENT OF THE YOUNG WHILE SUCKING.

For the first ten days or fortnight the mother will generally be able to support her litter without assistance, unless, as has been already observed, she is weakly, or they are too many in number; in either of which cases they must be fed from the first. When the young pigs are about a fortnight old warm milk should be given to them. In another week this may be thickened with some species of farina; and afterwards, as they gain strength and increase in size, boiled roots and vegetables may be added. As soon as they begin to eat, an open frame or railing should be placed in the sty, under which the little pigs can run, and on the other side of this should be the small troughs containing their food; for it never answers to let them eat out of the same trough with the mother, both because the food set before her is generally too strong and stimulating for them, and, besides, the chances are they would not get a mouthful. Those intended to be killed for "sucking-pigs" should not be above four weeks old; most persons kill them for this purpose on the twenty-first or twenty-second day. The others, excepting those which are kept for the purpose of breeding, should be castrated at the same time.*

WEANING.

The age at which pigs may be weaned with the greatest advantage is when they are about eight or ten weeks old; many persons, however, wean them as early as six weeks, but then they seldom turn out so well. They should not be taken from the sow at once, but gradually weaned. At first they should be removed from her for a certain number of hours each day, and accustomed to be driven by hunger to eat from the trough; then they may be turned out for an hour without her, and afterwards shut up while she is turned out also by herself. Subsequently they must only be allowed to suck so often in the twenty-four hours; perhaps six times at first, then four, then twice, and at last only once; and meanwhile they must be proportionally better and more plentifully fed, and the mother's diet in a like manner diminished; thus will the weaning be accomplished without danger or evil consequences to either. Some persons have advised that the whole litter should not be weaned at once; we do not, however, agree with them, unless it should happen that one or two of the young ones are much weaker and smaller than the others; in such case, if the sow remains in tolerable

* Our friend and fellow-practitioner, Mr. Horsefield, of Wentworth, informs us that "sucking-pigs kept in piggeries having stone pavements are apt to have the white flux, a bowel-complaint very prejudicial to their growth. To prevent or cure them of this malady," he says, "let there be plenty of fresh earth strewn for them in the inner pigery, which they will eat with avidity, and thus be kept alive and in good condition."

condition, they might be suffered to suck for a week longer; but such a mode of proceeding should be an exception, not a general rule.

Pigs are more easily weaned than almost any other animals because they learn to feed sooner; but nevertheless this is always a somewhat critical period, and great attention must be paid to them if we would have them grow up strong, healthy animals. Their sties must be warm, dry, clean, well ventilated, and weather-tight. They should have the run of a grass meadow or paddock for an hour or two every fine day, in the spring and summer, or be turned into the farm-yard among the cattle in the winter, as fresh air and exercise tend to prevent them from becoming rickety or crooked in the legs.

Butter-milk, whey, and the refuse of the dairy, with boiled or steamed potatoes, pollard, and oat or barleymeal, may be given as food; also boiled cabbage and lettuce, macerated and bruised oats, barley, and even wheat; in short, the most nutritious and succulent food that circumstances will permit of, and a daily run at grass wherever it is possible. At first their food should all be given to them warm, and be tolerably soft, in order better to assimilate with the state of the digestive functions; gradually and soon they must be accustomed to take it cold, it being far better for them so when once they are used to it; and they must also learn to masticate their food.

Newly-weaned pigs require five or six meals in the twenty-four hours. In about ten days one may be omitted; in another week, a second; and then they must do with three regular meals each day.

But let it be understood that, while we would enforce the necessity of good and ample feeding, we highly deprecate all excess, and all stimulating, heating diet, such tending to vitiate the animal powers, often to lay the foundation of disease, and never to produce good, sound, well-flavoured flesh.

A little sulphur mingled with the food, or a small quantity of Epsom or Glauber's salts dissolved in the water, will frequently prove beneficial.

A plentiful supply of clear cold water should always be within their reach; the food left in the trough after the animals have done eating should be removed, and the trough thoroughly rinsed out before any more is put into it. Strict attention should be paid to cleanliness; indeed, many persons assert that there is no comparison in point of thriving between an animal well cleaned and repeatedly brushed and another that is left to itself; although both shall be in feeding and all other respects treated exactly the same, the latter will not weigh so much as the former by many pounds.

This treatment will bring them on to the time when the owner must separate those he intends for breeders from those which are to be fattened for the market. The boars and sows should be kept apart from the period of weaning.

The question of which is most profitable—to breed swine, or to buy young pigs and fatten them—will best be determined by the individuals who have to study it, for they know best what resources they can command, and what chance of profits each of these separate branches offers.

There was an interesting paper published some little time since in the "Farmer's Magazine," calculating the number of pigs, which, in the

course of ten years, may be raised from two one-year old sows. We give it verbatim, as many of our readers have probably never entered into such a calculation, or formed the least idea of the amazing quantity of animal food which may be derived from this kind of stock:—

“I am indebted to a worthy and sensible friend, and a friend also of the poor, for the following estimate of what I shall term ‘pig population,’ and set it in array against the increasing demands of the home population, which goes on at the rate of not quite $1\frac{1}{2}$ per cent. per annum—nay, little more than $1\frac{1}{2}$ by the last ten years’ census. I think, with the assistance of my above-mentioned friend, I can feed the super-numeraries well, and in this way, at all events, save their bacon. Would you credit the assertion that in ten years—ten short years—and from two breeding sows, many millions can be produced? Would you suppose (for I certainly had no conception of the fact) that more than the present or even anticipated population of the country for ten years to come is not equal to the number of pigs to be thus born and bred in the same period, if we choose? But I shall proceed to the proof and give the figures, which are unanswerable arguments when well founded. His calculation, then, is as follows, viz. that in one year two sows (one year old) will breed ten each, of which we shall assume that one-half are females, and so proceed on that assumed equality.

“The first year there will be males and females	-	-	-	20
From which take the males	-	-	-	10
And we have the result as breeders	-	-	-	10
At the second year, then, we may fairly take the same ratio of ten to each, viz.	-	-	-	10
				2)100
And it gives us a hundred males and females, leaving, consequently, for the third year, breeders	-	-	-	50
I shall now drop the text, and merely give the figures, the same principle applying throughout	-	-	-	10
Third year	-	-	-	2)500
				250
				10
Fourth year	-	-	-	2)2,500
				1,250
				10
Fifth year	-	-	-	2)12,500
				6,250
				10
Sixth year	-	-	-	2)62,500
				31,250
				10
				312,500

Seventh year	-	-	-	-	-	-	2)312,500
							156,250
							10
Eighth year	-	-	-	-	-	-	2)1,562,500
							781,250
							10
Ninth year	-	-	-	-	-	-	2)7,812,500
							3,906,250
							10
Tenth year, males and females	-	-	-	-	-	-	39,062,500

"I hope my friend has brought his pigs to a good market; but to equalize the supply, I shall, for the present purpose, take only the male half of the pig population for food, leaving the breeders to go on. In this way we can kill and eat ten the first year—no bad increase from two sows recollect; the second year, 50; the third, 250; the fourth, 1250; the fifth, 6250; the sixth, 31,250 (pork in abundance now;) the seventh, 156,250 (still more abundant;) the eighth, 781,250; the ninth, 3,906,250; and the tenth, when divided in like manner, the enormous number of 19,531,250 for food, without interfering with the breeders, who, I presume, by this time will probably require killing also. Now, I am not aware that much commentary is required on this prolific subject; every man who reads this short paper will at once draw his own conclusion from the facts. They are, however, of a very cheering description, and drawn from the breeding of one domestic animal only, and amply prove what abundant stores nature and the God of nature have provided for human subsistence. I shall close this paper with the sensible practical observation of my friend in reference to this subject, as, after all, it is in practice only that the benefits open to all are to be received by any. In the county of Kent, he informs me, there are 31,000 agricultural families or farmers. It is a very easy matter for each to keep two breeding-sows, which in three years would produce in round numbers 15,000,000 of pigs.

"In the fifty-two counties of England, he also adds, the number of agricultural families is 760,000; so that, by the same mode of calculation as for Kent, of every farmer keeping two sows, the produce would be, in the like period, 380,000,000 pigs. One good breeding sow to each would consequently produce 15,000,000. As I have said, and say again, is this all true? for if so, what prevents the immediate use of the same beneficial proceeding to every one, not even omitting the allotment tenant? What more easy and practicable than to breed on a small scale, or to join two or three families together, and thus diminish expense and increase profits? I throw out the hint, and hope that good may arise from a due consideration of the prominent facts already stated."

With the following valuable remarks by that well-known practical agriculturist and grazier, Arthur Young, we will conclude this chapter:—

"The breeding of swine being one of the most profitable articles in the whole business of a farm, the husbandman cannot pay too much attention to it. I shall, in as few words as the subject will admit, give an account of the best system to be pursued in this branch of his business. The farmer who would make a considerable profit by hogs must determine to keep a proper number of sows in order to breed many pigs; but this resolution ought to be preceded by the most careful determination to prepare crops proper for supporting this stock. The proper ones for that purpose are barley, buck, beans, peas, clover, potatoes, or carrots. In the common management, a farmer keeps only a sow or two because his dairy will do no more; but in the system of planting crops purposely for swine, a different conduct must necessarily be pursued. Potatoes, carrots, Swedish turnips, and cabbages, must be provided for the sows and stores from October till the end of May, by which time clover, chicory, or lucerne should be ready to receive them, which will carry them till the stubbles are cleared; so that the whole year is filled up with these plants, and the common offal of the barn-door and the corn-fields. When the sows pig, meal must be provided to make wssh by mixing it with water. This in summer will be good enough for their support, and in winter it must be mixed with boiled roots, oats, and pea-soup, for the young pigs. If cows are kept, then the dairy-wash is to be used in the above mixtures.

"Upon this system, a farmer may proportion his swine to his crops, or his crops to his swine; and he will find that for the whole year he should have about an equal quantity of roots and grass, and half as much corn as potatoes. For carrying the profit to the highest advantage, the sows should pig but twice a-year, that is, in April and August, by which means there will never be a long and expensive season for rearing pigs before they are put to the staple food of clover or potatoes, &c.; but this circumstance is much removed by the provision of crops raised expressly for the swine.

"Upon this plan the annual sale of lean hogs should be in October, the litters of April sold then as stores, and those of August kept till October twelvemonth to sell for baconers, if the farmer feeds none himself. The stock upon hand this month will therefore be the sows, and the pigs littered in the preceding August, all which should have roots from the store, and run at the same time in the farm-yard, for shacking the straw of the barn-doors. In proportion to what they find in this, you must supply them with roots, giving enough to keep them in growth."*

CHAPTER XII.

On Feeding Swine—Fat Pigs—Cattle Shows—Whey, Milk, and Dairy Refuse—Refuse and Grains of Distilleries and Breweries—Residue of Starch Manufactories—Vegetables and Roots—Fruits—Grain—Soiling and Pasturing Swine—Animal Substances as Food for them—General Directions for Feeding and Fattening.

THE establishment of agricultural societies and cattle-shows formed the commencement of a new era in the breeding of all domesticated

* Farmer's Calendar, 1804.

animals, and especially of swine, which had, previously to that epoch, been very much neglected. There cannot be a doubt but that the competition, the assembling together of breeders from all counties and even from abroad, the comparison of the different animals brought together, and the conclusions drawn in many minds, tend materially to the elucidation and advancement of the science of breeding. Persons resident in remote localities are apt to set up for themselves some particular standard of excellence, and make it the whole aim of their endeavours to obtain and develop certain points in an animal, and having done this they rest satisfied; but when the annual cattle-show places before them other and evidently superior animals, they perceive how much too limited, and often how erroneous, have been their views, and set to work afresh to improve upon the knowledge thus acquired.

But there is no good without its attendant evil. It was, doubtless, originally intended by those who established the distribution of prizes for certain kinds of stock, that the prize animal should be the most excellent as to its points, the most useful to the farmer, breeder, and butcher, and altogether the most profitable; but not that it should be the fattest! It is reported that, on Hannah More being asked what was the use of cattle-shows, she replied, "To induce people to make beef and mutton so fat that nobody can eat it." This certainly is the *abuse* of them, and in no class of animals is it carried to such an extent as in swine. The greedy propensities of the poor animal are worked upon; he is shut up, often in darkness, and fed and suffered to gorge himself until he can scarcely move or breathe, and often dies of suffocation, or is obliged to be killed, from the simple exertion of being brought to the show in the most easy and careful manner. A premium would be far better bestowed upon the most useful and profitable animal, the one most likely to make good bacon or pork, than on these huge masses of obesity, whose superabundance of fat is fit for little else but the melting-pot. As much money is often wasted on one of these monsters as would purchase food for half dozen really profitable animals. And to what purpose? Simply to test the elastic power of a pig's skin? "No," reply the advocates of this species of monomania, "but to discover which breeds can be fattened to the greatest size in the shortest time, and on the smallest amount of food." And to this plea we can only reply, that while we admit the value of such knowledge, we think it might be attained without the sacrifice of a fine animal, at much less expense, and far more satisfactorily. Let the animals be fat, but do not let them be a mere bladder of lard, "of shape undefined," every point lost and buried. It is fine and profitable breeds we require, not monstrosities. The grand aim of agricultural societies is to promote the improvement of the breeds, and consequently the profit of the breeder, and general advantage. We trust that this will shortly be fully understood and carried out, and the cattle-shows become, as it were, model-rooms, instead of mere exhibitions of over-fed, panting, unshapely beasts. But it is not our feeble voice alone which is raised against this unnatural stuffing: public attention has latterly been much called to this point; and among others, our merry critic Punch, who fails not to lash each passing folly of the age, has, as will be seen by the following epitaph, not been unmindful of this one:—

"Epitaph on a Prize Pig.

"HERE LIES
ALL THAT WAS EATABLE
OF A PRIZE PIG.

HE WAS BORN
ON FEBRUARY 1, 1845:

HE WAS FED
ON MILK, POTATOES, AND
BARLEY-MEAL:

HE WAS SLAUGHTERED
ON DECEMBER 24, 1846,
WEIGHING 20st. 9lbs.

STOP, TRAVELLER!
AND REFLECT HOW SMALL A PORTION
OF THIS VAST PIG
WAS PORK SUITABLE
FOR HUMAN FOOD."

Hurtrel D'Arboval, treating of Obesity, says, "There is, however no animal so liable to become over-fat, as the pig, and especially the Chinese and Siamese swine. Naturally inclined to corpulence and gluttony, they easily acquire an enormous bulk; and when fat has once begun to accumulate, the animal eats little, breathes with difficulty, becomes inert, unable to sustain his own weight, and deficient in sensation. We have seen wretched pigs so fat that they were obliged to be lifted or dragged out of the sty whenever it was necessary to move them. We have also made incisions in their buttocks, and even taken off portions of skin from their backs, without their betraying any sense of pain. We saw one hog that had lain for a considerable period on one side, too powerless or too inert even to shift its position, and when it was raised a large hole was perceived in that part of the back which had been undermost. This had been made by rats feeding and gnawing into the fat of the beast, evidently without its being in the least conscious of their proceedings.

"Animals that have been castrated are always more disposed to obesity."*

We will now proceed to consider the various modes of keeping and feeding swine and their relative value, and the other incidental matters which may develop themselves as we proceed.

Swine are generally fattened for pork at from six to nine months old, and for bacon at from a twelvemonth to two years. Eighteen months is generally considered to be the proper age for a good bacon-hog.

The feeding of pigs will always, in a great measure, depend upon the circumstances of the owner, upon the kind of food which he has at his disposal and can best spare, and the purpose for which he intends the animals. It will also be in some degree regulated by the season, it being possible to feed pigs very differently in the summer to what they are fed in the winter. During the former they can either be sty-fed or pastured, or both; and there is also a greater variety of vegetables and

* Hurtrel D'Arboval: Dictionnaire de Médecine et de Chirurgie Vétérinaire, vol. iii.

green food for them, as well as of dairy refuse; while in the winter they must be home-fed, and in most cases their diet limited to roots, peas, beans, or other such dried food, and wash composed of the scanty residue of the dairy, or supplied from the house or brewery.

WHEY, MILK, AND DAIRY REFUSE.

For sty-fed pigs the washings of the dairy, as butter and skim-milk, whey, &c., are excellent, and especially whey thickened with barley, or oat, or pea-meal, whey being more nourishing than skim-milk; the animals thrive and make flesh so well on it, that many farmers are of opinion that this mode of employing their sour milk is more profitable than making cheese. But when the swine have once become habituated to this kind of diet it must be continued, as they would fall off if put upon any other. There was a beautiful lot of Coleshill pigs exhibited at the last Smithfield Club Cattle-Show, belonging to the Earl of Radnor, aged twenty-one weeks, which had been fattened on forty-eight-bushels of barley-meal and six bushels of potatoes, with an adequate quantity of whey. Wherever, therefore, there are large dairies, swine may be most advantageously kept, the excellence of dairy-fed pork being incontestable.

WASH, GRAINS, AND REFUSE OF BREWERIES AND DISTILLERIES.

The refuse wash and grains and other residue of breweries and distilleries may also be given to swine with advantage, and seem to induce a tendency to lay on flesh, but not in too large quantities, or un-mixed with other and more substantial food; as, although they gain flesh rapidly when fed on it, the meat is not firm, and never makes good bacon.

Thäcr advises that the refuse of brandy-distilleries should always be diluted with water at first, otherwise the animals will reject it, or, if they take it, become giddy, and be unable to keep their feet; afterwards, the quantity of this food may be gradually increased till they are completely accustomed to it. Neuenhahn says that the refuse of the brandy-distillery cannot be given to the pigs too warm, or too soon after its removal from the still, and that it never heats their blood; but that, if it be allowed to get cold and stale, it is rather injurious than beneficial to them. On the other hand, many experienced distillers, who fatten large numbers of hogs, assure us that it requires great attention, and the employment of a man on whose care we can rely, to prevent this residue from being given to the animals while too warm, for it is then that it injures and materially retards their growth. It should be sometimes thick, sometimes diluted with water, and at others mixed with meal or pollard, in order, by thus varying the food, to keep up the appetite of the animals.

RESIDUE OF STARCH MANUFACTORIES.

The residue of the manufacture of starch, the products of the various washings which this precaution involves, and the refuse of wheat, are far superior to brewers' and distillers' refuse. Hogs fed upon these articles fatten more quickly, produce firmer flesh, more substantial

bacon, and a greater quantity of lard. At first the animals will often eat these matters with great avidity, and even to excess, and when this is the case they invariably become disgusted and refuse them after a time. The quantity must therefore be carefully regulated, and the troughs kept very clean. If this kind of food be used alternately with one of a different nature, the fattening will be effected with greater certainty. The quantity of this refuse collected at once is often greater than can be consumed at the time, and it is difficult to store it up, because its animal portions so soon putrefy. The only mode of preservation is to dry it, make it into cakes, and bake it.*

VEGETABLES AND ROOTS.

Cabbage and lettuce-leaves, turnip-greens, and bean and pea-haulm, may be given to pigs in moderate quantities with advantage, but these substances should be chopped up small and mingled in the wash, as the animals, being very fond of such food, will otherwise devour it too ravenously to be able properly to masticate it.

Almost all our common roots are well adapted for feeding pigs; carrots, turnips, parsnips, beet-root, and last, but not least, the potato, are all exceedingly nutritive, even when given in a raw state, but that cooking tends materially to increase their nourishing powers is a fact well attested by numerous experiments and general experience. Potatoes should be steamed, the other roots boiled. In Guernsey the parsnip is extensively used in the feeding of pigs, especially from September to Christmas, and eight perches of land, each producing on the average 250 lbs. of this root, are considered as the general allowance for fattening a pig in store order. But the flesh of animals thus fed is not so firm as that of pigs fed on pea or barley-meal with a slight addition of corn, and shrinks when boiled, instead of plumping. Carrots are considered by some persons to fatten swine more rapidly than any other root, and to impart a particularly delicate flavour to the flesh; they may be given raw. Potatoes are, however, the staple food in by far the greater part of England, and the whole of Ireland. They should be steamed, and then mashed with meal or pea-flower in whey or sour milk (where it can be had,) or in wash or clear water, and made of the consistence of porridge. The water in which the potatoes have been cooked should always be thrown away. This root should, however, only be given for a short time, as it is by no means a rapid fattener, and does not make firm good fat,—and never alone if it can be avoided. Turnips should never be given while any other kind of food can be obtained, as their effects are far from beneficial, and often quite the contrary. Beans and peas, both green, dried, and ground, or bruised and macerated, form excellent food. Peas are considered to produce firmer flesh, and to fatten quicker than beans. The grey pea is generally allowed to be the best adapted for swine, and to contain most nutrition. Experiments have been made with the blue pea, but hogs fed on it had always a tendency to diarrhoea. Every part of the pea, the haulm, the cods, and the peas themselves, may be used in feeding pigs. Sir John Sinclair found green beans also very advantageous food for swine; he gives preference to the Windsor bean, and advises

* Thüier's Principles of Agriculture.

that two or three successive crops of them should be sown in order to secure a constant supply from July until September.

In the "Quarterly Journal of Agriculture" we find an account of some experiments made with the view of testing the relative fattening powers of carrots, potatoes, peas, wheat, and buckwheat.

Five couples of pigs were separately put up to fatten :—

				Increase of Weight.	
To couple	1	was given	55 decalitres * of peas	22 st.	7 lbs.
"	2	"	233 " balls of wheat	24 st.	3 lbs.
"	3	"	96 " buckwheat	26 st.	10 lbs.
"	4	"	98 " boiled potatoes	20 st.	4 lbs.
"	5	"	175 " carrots	28 st.	2 lbs.

These results of the experiment are, however, unsatisfactory, because it is not mentioned whether the pigs were all of the same age and weight, nor is it stated whether the quantity of food marked in the table was as much as the pigs could consume.

We have always believed that peas were the most nutritious food that could be given to pigs, and this experiment confirms the belief, as may be seen on comparing the relative increase of weight obtained from the various kinds of food, viz. :—55 decalitres of peas gave an increase of 22 stone 7 lbs., or nearly 6 lbs. of increase of pork from 1 decalitre of peas ; whereas from boiled carrots only 28 stone 2 lbs. of increase were obtained from 175 decalitres, or about $2\frac{1}{2}$ lbs. from 1 decalitre, giving the advantage over the peas in the ratio of $2\frac{1}{2}$: 1. The next most nourishing food is buckwheat, which nearly gives 4 lbs. of pork from 1 decalitre. Boiled potatoes are next, giving nearly 3 lbs. of pork from 1 decalitre ; and the lowest quantity of pork is that obtained from the balls of wheat, which is as low as 1 lb. from 1 decalitre. Flour would no doubt fatten better than wheat, especially if the feeds were made into small dry balls of dough and frequently administered.

FRUITS.

With the exception of the acorn we have seldom a sufficiently abundant crop of fruit of any kind to admit of our making it an article of food for swine. When England was rich in forest land, the *mastage* or *pannage* of swine in these localities was a valuable privilege, for if the animals did not absolutely get fat, they were kept in fair condition at no expense to the owner beyond that of paying a person to look after them.

Hogs will eat the acorns and beech-mast greedily, and certainly thrive to a certain extent on this food, so far that it is an easy matter to fatten them afterwards. Parkinson says,—“ When I lived with my father, acorns were so plentiful in the woods one year, that they made the pigs sufficiently fat for bacon without any other food. The flesh was equally as good and as well-flavoured as that of other animals that had been fed on beans and peas.” Acorns that have become dry in the sun and air are far more profitable than those which are fresh fallen and green ; but the way in which they may be most advantageously employed is to bake or roast them, and then crush them, and either boil them to a pulp, or pour boiling water upon them and let it stand until cool : the addition of a little salt makes an exceedingly palatable food, which the animals

* A decalitre is equal to 15 pinta.

greedily suck up, and which tends far more to fatten them than the raw acorn would.

Beech-mast eaten alone makes the fat oily and impoverishes the lean, but when taken in conjunction with acorns the one fruit qualifies the other and the combined effect is good.

In many parts of the Continent where chestnuts are grown in large quantities they constitute a considerable item in the feeding of swine, and are exceedingly nutritious, especially when given at the latter part of the fattening process. They impart firmness and a delicate flavour to the meat. Few persons give chestnuts in a raw state; they are either roasted in an oven or macerated in boiling water. The same reason may be given here as will apply to all kinds of roots and fruits, not only when used as food for swine, but also for other animals, and even for the human being: they are rendered more digestible by cooking, divested of their crudeness, and thus better calculated to nourish the system without fatiguing or disordering its powers. Besides which there is a decided saving effected. Some even go so far as to calculate that cooked, or ground, or bruised food, goes as far again as that which is given in its natural state or merely cut up.

In America, where there is an abundance of apples and pumpkins, these fruits are given to swine: we quote an account related by a great breeder of these animals, who attaches much value to these two articles of food, which seems to testify their utility:—

“On the 10th of October twenty swine were put up to fatten, all of which were only in middling store order, in consequence of the scarcity of feed. The cows producing very little wash from the dairy, and the crop of apples being scanty this season, nothing had been given them during summer but a small orchard containing one acre and a-half of land (with the premature apples which fell,) in which was a pond of water, a very essential requisite to hogs, and one to which, under the powerful influence of the sun, they will resort for their chief comfort.

“The above twenty swine were divided into three lots and closely confined; we proceeded to fatten them by steaming 4 bushels of small potatoes, 12 bushels of apple pomace, 4 bushels of pumpkins, and 1 cwt. of buckwheat cornel, adding a little salt, the whole being well incorporated together while hot from the steamer, with a wooden pounder, and suffered to undergo fermentation before it was used as food: they were at the same time supplied with plenty of charcoal and pure water. While feeding them with the first steamer of the compound a more than ordinary moisture was observed on their litter, which was occasioned by urine: a knowledge of animal nature convinced the owner that any more than an ordinary flow would weaken the system, and retard the progress of fattening; and he attributed this evil to the steamed pumpkins acting as a diuretic, stimulating the kidneys and increasing the evacuation of urine. In the next steamer, therefore, 4 bushels of rutabaga were substituted for the pumpkins, which had the desired effect. This experiment afforded proof that a mixture thus compounded contains a larger mass of nutritive material ready prepared for the action of the stomach, and therefore producing flesh more rapidly than any other combination of food made use of. All the waste apples being used up, and there being a greater quantity of soft corn on hand than usual, that was given to the hogs, but instead of their condition improving they fell off,

and the owner was under the necessity of procuring two loads of apple pomace from his neighbours, and commencing the steaming and feeding again; it was continued with the same good effect until eight days before the animals were killed, during which latter period they were fed with sound corn; they were slaughtered on the 1st of December. The expense of fattening and the produce of pork were as follows:—

Dr.	Dolls.	Cts.
32 bushels of small potatoes, at 2s.	8	00
32 bushels of ruta-baga, including pumpkins, at 2s.	8	00
10 bushels of soft corn, at 4s.	5	00
10 cwt. of buckwheat, at \$1 per cwt.	10	00
20 bushels of sound corn, at 6s. 6d.	16	25
	47	25
Cr.	Dolls.	Cts.
By 40 cwt. of pork, at \$7½ per cwt.	300	00
Deduct expense.	47	25
Balance	252	75" *

It is true that we have not often a superabundance of apples; but still in years when the crop is plentiful, the windfalls, diseased or injured apples, and the refuse left after the making of cider, may be given to the pigs, and will prove a fair substitute for more expensive food, if not in itself peculiarly advantageous; especially when economy in the keep is more studied than a rapid system of fattening.

Nuts should never be given to swine; they make the fat soft and greasy, and impart a sweet, unpleasant flavour to the flesh. Pigs are, however, exceedingly fond of them; so much so, that when they can get nuts they care little to touch any other kind of food.

GRAIN.

There is nothing so nutritious, so eminently and in every way adapted for the purpose of fattening, as are the various kinds of grain; the only drawback is, that they are too expensive to be used to any great extent for this purpose, otherwise no animal should be considered as properly fattened unless some kind of grain had been given during the latter part of the time; as nothing tends more to create a firmness as well as delicacy in the flesh. It has been calculated that for every bushel, half of peas and half of barley, that a hog eats, it gains from nine to ten or eleven pounds of flesh.

Two pigs of about eight months old, were purchased and put up to fatten on the 23d of December, 1834; they then weighed 316 lbs. They were put into a warm sty and fed on rye and corn-meal, having three regular feeds per diem, of two quarts each, up to the following October, when they received three quarts at each feed, or nine quarts a-day for about a month. From that time until the 7th of December, 1835, a period of five weeks, their feeds were raised another quart, making now twelve quarts a-day. Besides this they had the refuse of the milk of two cows, and occasionally a very little green meat. When slaughtered, they weighed 81 st. 4 lbs. of 14 lbs. to the stone, which, allowing for one-third of offal, will amount to the gain of about 3½ lbs. of live weight

* The Cultivator, vol. ii. American Agricultural Magazine.

per day. They ate in the whole fifty bushels of rye and corn ground; in cold weather it was scalded and given to them warm, and in the summer put into the trough and milk poured upon it.*

There are also repeated instances in which the animals have increased in weight 2 lbs., 2½ lbs., and even 3 lbs. a day, while fed on barleymeal only, or barleymeal and peas, or potatoes; the relative prices, however, of grain and pork will always decide the question of the advantage of this mode of feeding far better than volumes of experiments or comments.

Barley and oats are considered to be best adapted for fattening swine. Some persons give the preference to oats, and where the grain is given whole they certainly are more digestible and less heating; but ground barley or barleymeal is universally allowed to be the most nutritious of all food.

There are various ways of giving grain to swine:—Raw and dry, roasted or malted, bruised and macerated, boiled, green, and *growey* or germinating wheat; and, lastly, ground to meal or farina. Of these the first two are the least advantageous, as the grain is then often but imperfectly masticated, and consequently produces indigestion. Wherever it is thus given the animals must be well supplied with water. A little whole grain given once a-day, or every other day, to pigs fed on barleymeal, is considered to be beneficial and add to the firmness of the flesh.

Macerated grain is better, or rather would be if the animals would eat it freely, which they seldom will do. Its fattening properties are increased if, after maceration, it is suffered to lie and germinate, and then dried or malted; or left to stand in the water until the whole turns sour.

Many persons consider that grain boiled until the husk bursts is better adapted for feeding swine in this form than when ground, and is likewise more economical; the only difference, however, in this latter respect, will depend upon whether the expense of having it ground be greater or less than that of the fuel necessary to boil it.

It is our opinion that the best, most economical and advantageous form in which grain can be used is that of meal moistened with water, whey or sour or skim-milk, into a kind of soup or porridge. The fluid, whatever it may be, which is in the first place poured upon it, should never be more than lukewarm, and had better be quite cold; hot or boiling liquid will cause the meal to conglomerate into lumps of paste, not easily dissolved, and very likely to bring on indigestion. The Rev. Arthur Young, in his work on fattening cattle and swine, gives the following directions as to the best method of employing this kind of food:—"The most profitable method of converting corn of any kind into food for hogs is to grind it into meal, and mix this with water in cisterns, in the proportion of five bushels of meal to one hundred gallons of water; stir it well several times a-day, for three weeks in cold weather, or for a fortnight in a warmer season, by which it will have fermented well and become acid, till which time it is not ready to give. It should be stirred immediately before feeding. Two or three cisterns should be kept fermenting in succession, that no necessity may occur

* The Cultivator, vol. ii.

of giving it not duly prepared. The difference in profit between feeding in this manner, and giving the grain whole, is very great, so great that whoever tries it once will not be apt to change it for the common method."

Thäer informs us that ground corn or coarse meal made into sour dough (by mixing the farina or meal with warm water and a little yeast, and then suffering it to stand in a high temperature until it turns sour, which it will do in the course of a day,) is a better and more profitable mode of feeding swine on grain than any other. A portion of the sour dough is then softened with water and given to the pigs, with a small portion of ground corn or barleymeal stirred up in it. The animals relish this food exceedingly, and thrive rapidly upon it; but if the dough is given alone, although they seem to make flesh as quickly, the meat is flabby and the fat porous. Peas might be added instead of the farina or meal, or a little whole barley or oats.

The same author likewise says:—"Some persons appear to be exceedingly successful in fattening their pigs on bread made of coarse rye or barleymeal. They cut this bread in pieces, dry it in an oven, then soak it in water, mash it, and give it to the animals in the form of porridge. Where sour milk or whey can be substituted for water, this food is said to surpass all others for quickness and efficacy in fattening, and for the goodness of the flesh and fat it produces."

Indian corn has latterly been employed in England with great success in feeding swine, and that it is highly nutritive and well adapted for the purpose there can be no question; here, as in most cases, the price will in a great measure decide the advantage or non-advantage of using it.

Maize is equal if not superior to any kind of grain for fattening, and is extensively used on the Continent and in America, where this article can readily be obtained. The best way is to give it quite at the latter end of the fattening period in small quantities, as a handful or a few ears. It may be given in its natural state, as pigs are so fond of it that they will eat up every seed. The pork and bacon of animals that have been thus fed is peculiarly firm and solid.

Rice is another valuable adjunct in fattening swine; we will quote in support of its properties the following account, given by an amateur pig-breeder:—

"We purchased from the government stores several tons of damaged rice at a very cheap rate; with this we fattened our pigs, and such pork I never saw before or since; the fat was as firm and solid as the lean, and the flavour of the meat very superior.

"The way in which the rice was prepared for food was as follows:—My copper held forty gallons; in the afternoon it was filled or nearly so, with water; as soon as the water boiled, the fire was raked out, two pails of rice immersed in the water, and the whole covered closely down and left to stand until the morning. On the following day the copper was emptied of its contents, which consisted of a thick jelly, so firm as only to be taken out with a shovel; and on those contents the pigs were fed. The effect was perfect.

"As to the economy of the plan, that of course must be a matter dependent upon circumstances; we found it more profitable than almost any other kind of food we could have given, from the price at which

we were able to purchase the rice, and its goodness. From some slight experiments, I am induced to think that equal parts of rice jelly and mashed potatoes would constitute an excellent food."

Another person who tried rice as a food for pigs put up two weighing five stone each, and fed them entirely on equal parts of boiled rice and steamed potatoes. At first they progressed but slowly, but eventually attained the weight of fifteen stones each. Their flesh was fine and delicate, the fat white and firm, and the flavour of both was excellent.

Under the head of grain some writers consider beans, peas, and tares; we have already spoken of the first two when treating of vegetables, and given it as our opinion that pea-meal is little if at all inferior to barley and oatmeal. The addition of a few dry peas to the porridge made of barleymeal and whey is advantageous; and many persons consider good pea-soup to be equal to any thing in its fattening powers.

Bran or pollard, unmixed with any farinaceous particles, conduces but little to fatten an animal; it has been considered that fermentation will increase and develop their nutritive properties, but we should be sorry to be compelled to rely solely on either of these two substances.

SOILING AND PASTURING SWINE.

We have already spoken of the advantage of a run at grass to swine of all ages, and permanent pastures are those best adapted to this purpose. Soiling, or feeding pigs on cut green meat, has also its advantages, and is very much practised wherever there are crops and facilities for so doing. The best artificial grasses and green meat for swine are clover, lucerne, chicory, sainfoin, vetches, tarss, and bean and pea-haulm. Some persons feed their swine on these matters in the fields; but it is a far better practice to turn them into yards or small enclosures, and there have the green meat brought to them, as by this means the animals are not able to wander about so much, exhausting their strength, and feeding in a desultory manner, but are kept quiet, and their dung more concentrated, especially if good litter or earth is laid down to receive and absorb it.

This feeding on green meat for awhile cools and purifies the blood, and keeps the animals in fair store condition, though it tends but very little to fatten them: where it is intended that it shall perform that office as well, it must not be simply cut green from the field and thrown to them, but chopped up small and salted, and mixed with the screenings of corn, or pollard, or meal, or roots, and moistened with some kind of wash, and left to ferment.

Clover, hay, or dried vetches may be also given to swine, chopped up small, and in wash; the former with undoubted advantage, for clover and lucerne are allowed to be exceedingly nutritive to swine; but many persons consider vetches, whether green or dried, as heating.

ANIMAL SUBSTANCES.

There cannot be a doubt but that these are highly fattening in their nature, and also that swine, being somewhat allied to the carnivora, will greedily devour them; but the question is, Do they not tend to make the flesh strong and rank, to inflame the blood, to create in the

animals a longing for mors of such food, and thus lead them to destroy fowls, rabbits, ducks, and even the litters of their companions? Many will give blood, entrails, scraps of refuse meat, horse-flesh, and such like, to swine, but we should decidedly discourage such practices; the nearest approach to animal food we would admit should be pot-liquor, and dairy refuse. Animal food is bad for every kind of swine; and tends to make them savage and feverish, and often lays the foundation of serious inflammation of the intestines.

GENERAL DIRECTIONS FOR FEEDING AND FATTENING.

Regular hours of feeding rank among the first of the rules which ought to be observed; the pigs will soon learn to expect their meals at certain times, and the stomach will be ready for it; irregularity will therefore irritate the digestive powers, and prevent so much benefit being derived from the meal when it does come.

Small meals, and many of them, are preferable to few and large ones, for swine are very apt to gorge and over-eat themselves, or, if any be left in the trough, to return to it by fits and starts until it is all gone; in both cases the digestive functions are impaired, and the process is not fully and beneficially performed. The best remedy for indigestion is to let the animals fast for four-and-twenty hours, and then to give them a small quantity of dry food, as barley or peas, whole and salted, and let them fast four or five hours more before resuming their usual food.

Pigs always eat more when first put up to fatten* than they do afterwards; therefore the most nutritious food should be reserved until they are getting pretty fat. And at that period the food must be varied, for the appetite being diminished, it becomes necessary to excite it by variety; and, besides, the same aliment constantly given palls upon the stomach, and is incapable of supplying in itself all the various kinds of nutriment required by the increased and altered state of the body.

It will be found advantageous occasionally to mingle a little sulphur or powdered antimony with the food of swine put up to fatten; about half an ounce once in ten days will usually be sufficient. These medicines tend to purify the blood, facilitate digestion, and maintain the appetite.

An American writer states that he has found gall-nuts, bruised and mingled with charcoal, to act most beneficially on the health of swine while being fattened; and also recommends that they should always be allowed to root in the earth of a small yard attached to the sty each day, and, if they will, eat some of the earth, which will be good for them. An intelligent writer in the "Quarterly Journal of Agriculture" states, that on the Duke of Montrose's estate, the pigs have ashes and cinders given them occasionally to correct the acidity of the stomach; and that they are frequently turned out to a piece of ground sprinkled with lime, which they root in and eat; or else, if this is not possible on account of the weather, a little magnesia is now and then mingled in the milk. These simple precautions are always more or less necessary to animals that are highly fed and have little or no exercise, and we should recommend them to the attention of all owners of pigs.

Cleanliness is another *sine quâ non*.* There is no idea so utterly

without foundation as the common one "that pigs love dirt." and that these animals thrive best in the midst of filth. We will quote one anecdote out of the many which have come to our knowledge, in refutation of this absurd opinion:—"A gentleman in Norfolk put up six pigs of almost exactly equal weight, and all in equal health, to fatten; treated them, with one exception, all exactly the same, and fed them on similar food, given in equal quantities to each, for seven weeks. Three of these pigs were left to shift for themselves so far as cleanliness went, and the other three were carefully curried, brushed, and washed. These latter consumed in the seven weeks less food by five bushels than the other three, and yet, when killed, weighed more by 2 stone 4 lbs. on the average."

It should be the duty of some one person to keep the skins of the pigs put up to fatten—indeed we would rather say, of all the pigs kept—perfectly free from mud, dust, or filth of any kind; and this will best be done by taking care that they always have clear water to bathe in within their reach, clean litter to lie upon, are occasionally combed and brushed, and that the sty is always kept free from filth. Nothing is so likely to engender lice and diseases of the skin as for it to be suffered to remain in a dirty state. It is true that the maintenance of cleanliness will cost some trouble and expense, but every owner of pigs will best consult his own interests by attention to this point.

The best period for fattening pigs is the autumn; then almost every kind of food is to be had in plenty, as well as in perfection; the weather is neither too hot nor too cold; and the humidity generally prevalent at this season acts beneficially upon the skin and tissues, and as it were lubricates the whole animal economy. Besides, they are ready to be slaughtered at the period when this can be done with most advantage; when the lowness of the temperature allows more time, and consequently enables the owner to turn the flesh to the greatest advantage; whereas in hot weather the meat must be salted or pickled, eaten or disposed of immediately, or it turns off and is spoiled. In the immediate neighbourhood of large towns alone will it be found advantageous to fatten pigs so as to have them ready to kill in the summer; there the prices which can often be obtained may compensate the dealer for the difficulty and risk he undergoes; but even the facilities afforded by railways will hardly do this to those who reside in remote localities, as here the expense of the transmit has to be added to the other items, and the risk is increased by close packing.

The best kinds of food for fattening pigs are:—

Milk or whey mixed with barley, oat, corn, or pea-meal, or with boiled and mashed potatoes.

Potatoes and rice; potatoes and meal of any of the above kinds, or mashed potatoes and whole grain.

Peas given whole, or crushed, or in the form of soup, and either alone or mixed with barley meal or potatoes.

Carrots and parsnips; and especially boiled carrots, which some persons consider to be the most nutritious and fattening food that can be given to swine.

Pasturage on clover, lucerne, or sainfoin, or a run in the stubble of corn-fields immediately after the crop has been cut and got in.

Beet-root and ruta-baga are good; but should only be given when other roots cannot be easily obtained.

And lastly, grain itself, as corn, barley, and oats, but not rye.

An American correspondent gives the following recipe for "an exceeding nutritious food for hogs;" but it is one which circumstances will not often permit us to make use of:—Boil Irish potatoes, pumpkins, and apples until they are soft; mash them all together, taking care thoroughly to mix and incorporate them, and add a little salt to the compound; swine will be found to relish this food highly, and thrive uncommonly well upon it."

A small portion of salt should always be mingled in whatever food is given, as it tends to stimulate the appetite as well as the digestive functions; and an ample supply of good water for drinking be kept within the reach of every animal.

Indian corn, buckwheat, rice and maize, may doubtless be given with advantage, and are in themselves highly nutritious; but they cannot be reckoned as among the kinds of food generally in use, as, unless under peculiar circumstances, they are too expensive, and not always to be obtained at all.

Turnips, cabbage, lettuce, and beans, are not so much adapted for fattening as the kinds of food above enumerated, although these matters often form valuable additions to the keep of store-pigs.

CHAPTER XIII.

On the Proper Construction of Piggeries—Ventilation—Description of Mr. Henderson's Sties—Cooking Apparatus—Curious Contrivance for Feeding Pigs—Description of the Piggery at Prince Albert's Home Farm—Description of a Piggery at Lascoed—Advantages of Cleanliness—Pig-keeping in Mexico.

THERE are few things more conducive to the thriving and well-being of swine than airy, spacious, well-constructed sties, and, above all, cleanliness. The old prejudices—that any place was good enough to keep a pig in, and that filth and pigsties were synonymous terms—are now passed away, and the necessity of attention to this branch of porcine economy generally recognised.

Formerly swine were too often housed in damp, dirty, close, imperfectly built sheds; this was an error, and a fruitful source of disease, and of unthrifty animals.

In large establishments where numerous pigs are kept, there should be divisions appropriated to all the different kinds of pigs; the males, the breeding sows, the newly weaned, and the fattening pigs should all be kept separate; and it were as well that in the divisions appropriated to the second and last of these four classes, there should be a distinct apartment for each animal, all opening into a yard or enclosure of limited extent. As pigs require warmth, these buildings should face the south, and be kept weather-tight and well drained. Good ventilation is also important, for it is needless to expect animals to make good flesh and retain their health unless they have a sufficiency of pure air. The blood requires it to give it vitality and free it from impurities, as much as the stomach requires wholesome and strengthening food, and

when it has it not, becomes vitiated, and impairs all the animal functions.

“The blood, the fountain whence the spirits flow,
The generous stream that waters every part,
And motion, vigour, and warm life conveys
To every moving breathing particle,”—

becomes contaminated by those ærial poisons given out by the decaying vegetable matter, rotten or damp litter, accumulations of dung, and animal exhalations engendered by ill-ventilated sties. These noxious gases are inhaled by the breath, and absorbed by the skin, until they enter the circulation, and impair its vivifying fluid. It is by the action of the atmospheric air that venous blood is converted into arterial, freed from all its impurities, and rendered fit to sustain all the vital functions; hence it must be at once evident that if this important agent is in the first place contaminated, its action must be impaired and its effects empoisoned. Besides, bad smells and exhalations injure the flavour of the meat.

Damp and cold floors should also be guarded against, as they tend to induce cramp and diarrhœa; and the roof so contrived as to carry off the wet from the pigs.

The walls of a well constructed sty should be of solid masonry; the roofs sloping, and furnished with spouts to carry off the rain; the floors either slightly inclined towards a gutter made to carry off the rain, or else raised from the ground on beams or joists, and perforated so that all urine and moisture shall drain off. Bricks and tiles are much used for the flooring of sties, but are objectionable, because, however well covered with litter, they still strike cold; wood is far superior in this respect; as well as because it admits of those clefts or perforations being made which we have just recommended, and which not only serve to drain off all moisture, but admit fresh air as well. The value of the litter and dung as manure, must always be borne in mind, and all things so arranged that none of it shall be wasted.

The door of each sty ought to be so hung that it will open inwards or outwards, so as to give the animals free ingress and egress; and to do this it should be hung across from side to side, and the animal push it up to effect its entry or exit, for if it were hung in the usual way it would derange the litter every time it opened inwards, and be very liable to hitch. If it is not intended that the pigs shall leave their sty, there should be an upper and lower door, the former of which should always be left open when the weather is warm and dry, while the latter will serve to confine the animal.

There should also be windows or slides which can be opened or closed at will, to give admission to the fresh air, or exclude rain or cold.

Mr. Henderson's description of his sties is more lucid and practical than mere vague directions, we will therefore give it in his own words:—"The plan which I recommend is as follows. Have a house thirty feet by fifteen, with four doors all opening outwards, and three partition walls through the house, viz. a wall between each of the doors, dividing the house into four compartments. The two middle ones I use for eating-rooms, and the others for sleeping apartments, having an inner door between each eating and sleeping apartment. By this

plan the keeper is enabled to get the eating-chambers swept out, the troughs cleaned, and the food put into them without disturbing the swine or being disturbed by them. There should be a division wall having a door in it through each sleeping apartment; in the hinder part should be the litter; and the front and smaller compartment, through which the animals must pass to get to their food, may be used by them as a kind of necessary, for these animals will never defile their beds if they can avoid it.

"The following is the most convenient manger for their food. Let it be as long as the house is wide, and fixed against the middle wall; in form similar to a horse manger, but not so deep, and it must be divided into twelve divisions by partition boards four feet in length or height, and a little broader than the manger is wide; thus a number will feed as well and as quietly together as two or three. Before every meal the trough should be well washed and the place swept, and once in the day a little fresh litter placed in the sleeping-chambers. Each of these sleeping and eating-rooms may be temporarily divided into two, should it be requisite. The sleeping-rooms should be dark, as animals fatten much more rapidly when they lie down and sleep after each meal than they do when they wander about. There should be a square yard to each piggery, well paved and drained, as should the sties also be; and, where it is possible, an enclosure or a small piece of ground adjoining is exceedingly useful.

"Those who have space to admit of it will find it advantageous to have five apartments instead of four, and in the fifth or central one to have a boiler to prepare the food, and chests and lockers to contain the various stores."*

Parkinson advises that in the yard or enclosure before every piggery should be "a rubbing-post, or, what is still more beneficial, two posts having a pole between them similar to a horse's leaping-bar, but not revolving; this pole should be raised or let down to the height of the pigs, as the rubbing of the animals against it causes a freer circulation of blood, the same as the flesh-brush does to human-bodies."†

In all large establishments there should be a proper apparatus for cooking, mixing, and preserving the food. For this a boiler and steamer will be requisite, and some two or three tanks which may be made of bricks plastered over on the interior to prevent leakage, and fixed in the ground. Wherever it can be managed, the troughs should be so situated that they can be filled and cleaned from the exterior without interfering with or disturbing the animals at all, and for this purpose the following very simple contrivance has been recommended:—"Have a flap or door with swinging hinges made to hang horizontally over the trough, so that it can be moved to and fro, and alternately be fastened by a bolt to the inside or outside of the manger. When the hogs have fed sufficiently, the door is swung inwards and fastened, and so remains until feeding-time, when the trough is cleaned and refilled without any trouble, and then the flap drawn back and the animals admitted to their food." Some persons cover the trough with a lid having as many holes in it as there are pigs to eat from it. This

* Henderson on Swine.

† Parkinson's Live Stock, vol. ii.

is by no means a bad plan, for then each pig selects his own hole and eats away without interfering with or incommoding his neighbour.

We cannot deny a place to the following curious method of feeding swine, although we by no means recommend it, as it would encourage a desultory mode of feeding—a thing always to be avoided:—

“The ingenious Rich. Fermore, of Tusmore,” says Dr. Plot, “showed me a curious contrivance he had for feeding his swine, which constantly have their meat from a vessel like the hopper of a mill placed over the sty, into which a certain quantity of beans having been put sufficient fat to so many hogs, these continually descend about half way down the sty in a large square pipe, which then divides itself into six smaller ones, which terminate each of them in a small trough just large enough to admit the nose of a hog, and come all of them with their ends so near the bottom that there is never more than a handful of beans in the trough at a time, which being taken away by the hog, there follows another, and so on: and he having drawn a rivulet of water through the sty, the daily trouble of waiting on the hogs is saved, the animals are constantly kept supplied, and are unable to waste or dirt their food.”*

We are indebted to the kindness of a friend for the following account of the Royal piggery, at the Home Farm at Windsor. It consists of an oblong slated shed, of sufficient length and breadth to contain about two dozen sties, of somewhat larger dimensions than ordinary pig-sties, and arranged in two rows with a broad walk between them, from which the spectator looks into the sties on the right and left of him. Each sty has an in-door and an out-door apartment, the former having a wooden coverlid to it, going upon hinges like the lid of a cornbin, instead of a roof, which may be raised to any height in hot or close weather, so as to admit any influx of air required, or even be thrown back if necessary. The sties are paved with brick, both within and without doors, and their floors slightly declivitous.

The following is a description of a piggery at Lascoed Pont Senny, planned and executed by Mr. J. Donaldson, Isnd steward to A. M. Storley, Esq., Brecon, South Wales:—“This piggery is constructed for the purpose of breeding and feeding on a scale to suit a farm of six hundred acres of turnip soil in an inland situation, where convenient markets render easy the disposal both of fat and lean stock. There are seven sties at the end of the steaming-house which accommodate a boar and six brood sows, which are calculated to produce yearly one hundred pigs, sixty of which will be fattened from September to April in fifteen sties, placed in two parallel rows, and made to contain two hogs in each apartment. The rest are sold as stores. The yearly rental is from 200*l.* to 250*l.*, according to the prices of the produce. The steamed food consists of potatoes and meal, with grain to finish, and is conveyed to the sties along a paved road or path, in a small four-wheeled wagon. The steamer also cooks potatoes for the working horses, and chaff for milch cows, and thus applies the original cost to several purposes, and fully employs a man. The store pigs are fed in summer with clover and vetches, and in winter with roots either raw or steamed. Water is brought to the steaming-house in a pipe from

* Plot's Natural History of Oxfordshire, 1677.

the farm-yards, which are all supplied by ball-cocks from elevated casks fed by a forcing-pump. A pipe underneath conveys the water from the potato-washer to the pond in the store-yard, where it passes to the lower curve of the yard, and then meeting with the collected moisture of the whole area of the piggery, falls through an iron grate into a paved culvert, and is conveyed to the manure-pit, to which the liquid of the farmery is collected and brought by a drain; along the side of the road are sheds opening into the store-yard. The cost of erecting a piggery like this will vary from 80% to 100% according to the price of labour and materials, and to whether the roofs be tiled or slated. The steaming-house has an upper floor to serve as a store-house for grain, meal, roots, &c.

The piggery should always be built as near to that part of the establishment from which the chief part of provision is to come as possible, as much labour will thus be saved. If the dairy is to supply this, let it be as near as may be to that building; or if it is to come from a brewery or distillery, then let it be near to them.

Care must also be taken to preserve the dung and urine, and some place fixed in which these matters can be stored for manure. Wherever the swine are regularly and well managed, this will not be difficult, for the animals will always, if they can lay their dung at a distance from the place where they sleep or feed. A small paved yard, somewhat sloping, and with a gutter to serve as a receptacle, will best answer this purpose, and thence it can be daily removed to the proper heap or tank.

We have been told of a gentleman who keeps only a few pigs for his own use, and has a double sty for them, by which means he is enabled to keep them exceedingly clean and sweet. Every morning the pigs are changed from one into the other, so that each sty remains unoccupied for four-and-twenty hours, during which time it is thoroughly cleaned out, and of course becomes well aired and free from all unpleasant smell. And well do we remember the pleasure with which we used to view the pigs and sties of an old friend of ours, now no more. A door leading out of his beautiful flower-garden brought us to these equally well-tended objects of his pride. The sties were always kept whitened on the inside, the slooping floor carried off all moisture to a deep gutter running between the sty and the square-paved yard, each of which inclined towards it; a trough ever stood with water clear as crystal for them to drink, and the animals themselves were, by washing, currycombing, and perfect cleanliness about them, as neat and sleek as a lady's lap-dog. They were, in fact, pet pigs. Nor are we without pleasurable reminiscences of delicate spare ribs, loins, and legs of pork and delicious sucking-pigs.

Washings, combings, and brushings are valuable adjuncts in the treatment of swine; the energies of the skin are thus roused and the pores opened, consequently the healthful functions are aided, and that inertness so likely to be engendered by the lazy life of a fattening pig counteracted. We cannot close this chapter without quoting the following account of the mode of keeping pigs in Mexico:—

“Fine breeds of these useful animals are kept by many persons of wealth, as an article of trade, in the city of Mexico; and the care and attention paid to their cleanliness and comfort so far exceed any thing I

have seen elsewhere, that a short account may be useful by furnishing hints to our farmers, brewers, distillers, &c., by whom large numbers of these valuable animals could be and are conveniently kept. The premises where the business is carried on are extensive, consisting in general of a good dwelling-house, with a shop, slaughter-house, and places for singeing the pigs, large bowls for rendering the lard, salting and drying rooms, and lard-rooms, with wooden bins for containing the rendered fat, which is an article of great consumption in Spanish cookery, being used as a substitute for butter. There is also a soap manufactory, in which the offal fat is manufactured, and apartments where the blood is made into a kind of black-pudding, and sold to the poor. Behind all these are the sties for the hogs, generally from eight hundred to one thousand in number, which occupy a considerable range of well-built sheds about thirty feet deep, with the roofs descending very low, and having the entrance through low arches, before which is an open space the whole length of the yard, and about twenty-four feet wide, in the centre of which is a kind of aqueduct built of stone, and filled with clear water supplied from a well at the end of the premises. The hogs can only put their noses into this water through holes in the wall, which prevents their dirtying it, as it passes through the whole division of the yard. This is the only liquid given them, and their food is maize or Indian corn, slightly moistened, and scattered at stated hours on the ground, which in the yard, as well as the place where they sleep, is kept perfectly dry and clean. They are attended by Indians with every possible care. There is a cold bath on the premises, which they are obliged frequently to use, as cleanliness is considered essential to their acquiring that enormous load of fat from which the principal profit is derived. Their ease and comfort seem also in every respect to be studiously attended to; and the occupation of two Indian lads will cause a smile on the countenances of my musical readers, when they are informed that they are employed from morning till night in settling any disputes or little bickerings that may arise among the happy inhabitants of this community, either in respect to rank or condition, and in singing them to sleep. The boys are chosen for the strength of their lungs, and their taste and judgment in delighting the ears and lulling the senses of this amiable harmonic society; they succeed each other in chanting during the whole day, to the great delight and gratification of their bristly audience, who seem fully to appreciate the merits of the performers."

CHAPTER XIV.

Pigs, Profit of, to the Butcher—Sucking-pigs—Pork-butchers—Pig-killing at Rome—Pickling Pork—Bacon: Mode of Curing in Hampshire—Buckinghamshire—Wiltshire—Yorkshire—Westphalia—America—Brine a Poison for Pigs—Quantity of Bacon, Ham, and Salt Pork imported during the last Three Years—Importation of Swine—Pig's Dung as Manure.

THERE is perhaps no animal so entirely profitable to the butcher as the pig. Scarcely an atom of it but is useful. The offal is so small as not to be thought of in comparison with that arising from cattle and sheep. The feet, the head, and even portions of the intestines are saleable for food and eagerly purchased by epicures; the scraps and trimmings of the meat make delicious sausages, pork pies, and other such savoury dishes; brawn, too, is another of the delicacies we owe to the much despised pig; the fat, or lard, is invaluable to cooks, confectioners, perfumers, and apothecaries; pigs' bladders meet a ready sale; the skin is available for pocket-books and several purposes; and the bristles form by no means an inconsiderable item in the tables of imports and exports, and are used by shoemakers, as well as in the manufacture of brushes, &c. Lastly, the flesh in the form of fresh or pickled pork, ham, and bacon, constitutes the chief food of thousands of human beings in all parts of the globe.

In France, from one-half to two-thirds of the meat consumed by the poorer and middling classes of the provinces is pork. In Ireland, the peasantry and many of the middle-men scarcely know the taste of any other kind of meat. In most of our Channel Islands pork constitutes the staple animal food of the labouring classes and small farmers; and in America, and especially among the new settlements and backwoods, it is often the only animal food for the first few years of the settler's life.

SUCKING-PIGS.

In our own country, "sucking-pigs" too are in great esteem, and will, at their season, fetch a very high price. Charles Lamb, in one of his inimitable 'Essays of Elia,' declares, "Of all the delicacies of the whole *mundus edibilis* I will maintain this to be the most delicate.

"I speak not of your grown porkers—things between pig and pork—these hobbydehoys; but a young and tender suckling, under a moon old, guiltless as yet of the sty; with no original speck of the *amor immunditiæ*, the hereditary failing of the first parent, as yet manifest; his voice as yet not broken, but something between a childish treble and a grumble, the mild forerunner or *prælude* of a grunt.

"*He must be roasted.* I am not ignorant that our ancestors ate them seethed or boiled; but what a sacrifice of the exterior tegument!

"There is no flavour comparable, I will contend, to that of the crisp, tawny, well watched, not over-roasted, *crackling*, as it is well called; the very teeth are invited to their share of the pleasure at this banquet, in overcoming the coy, brittle resistance, with the adhesive oleaginous

—Oh, call it not fat!—but an indefinable sweetness growing up to it—the tender blossoming of fat—fat cropped in the bud—taken in the shoot—in the first innocence—the cream and quintessence of the child-pig's yet pure food; the lean, no lean; but a kind of animal manna, or rather, fat and lean (if it must be so) so blended and running into each other, that both together make but one ambrosian result, or common substance.

“Behold him while he is doing! it seemeth rather a refreshing warmth than a scorching heat that he is so passive to. How equally he twirlleth round the string. Now he is just done. To see the extreme sensibility of that tender age; he hath wept out his pretty eyes—radiant jellies—shooting stars. See him in the dish, his second cradle; how meek he lieth! wouldst thou have this innocent grow up to the grossness and indocility which too often accompany maturer swinehood? Ten to one he would have proved a glutton, a sloven, an obstinate, disagreeable animal, wallowing in all filthy conversation—from these sins he is happily snatched away.

Ere sin could blight or sorrow fade,
Death came with timely care.

His memory is odoriferous: no clown curseth; whilst his stomach half ejecteth the rank bacon; no coalheaver bolteth him in reeking sausages: he hath a fair sepulchre in the grateful stomach of the judicious epicure, and for such a tomb might be content to die.

“Pig—let me speak his praise—is no less provocative of the appetite than he is satisfactory to the criticalness of the censorious palate. The strong man may batten on him, and the weakling refuseth not his mild juices.

“Unlike to mankind's mixed characters, a bundle of virtues and vices, inexplicably intertwined and not to be unravelled without hazard, he is—good throughout. No part of him is better or worse than another. He helpeth, as far as his little means goeth, all around.”

Sucking-pigs should be killed at from a fortnight to three weeks old. The Chinese breed furnishes the most delicate and delicious “porklings.” They should be stuck; all the blood suffered to drain out; scalded and scraped gently; and the bowels taken out, and the inside sponged dry and clean.

The alterations latterly effected in the breeds of swine have tended materially to improve pork, and to render it more sought for and valued. We can recall to mind when the thought of pork was associated in our minds with visions of coarse-grained meat and oily fat, and with forebodings of a fit of indigestion. Nothing could tend more effectually to banish such fancies than a sight and taste of the small, fine-grained joints, delicate as poultry, and of excellent flavour, which have taken the place of those ungainly legs and Brobdignagian loins and hands of “olden times.”

And with the improvement of the meat has grown an increased demand for it. Formerly, ay, as lately as within the last five and twenty years, the trade of “pork-butcher” was unknown in almost all our country towns, even in those of some considerable importance; it is no longer so; there are now few places of any size or note which have not on an average one pork-butcher to every two or three meat-butchers;

and in all smaller places pork is generally to be procured wherever other meat is sold.

PIG-KILLING.

A pig that is to be killed should be kept without food for the last 12 or 16 hours; a little water must, however be within his reach. Mr. Henderson advises that in order to prevent the animal from struggling and screaming in the agonies of death, it should in the first place be stunned by a blow on the head. Some advise that the knife should be thrust into the neck so as to sever the artery leading from the heart, while others prefer that the animal should be stuck through the brisket in the direction of the heart, care however being taken not to touch the first rib. The blood should then be suffered to drain from the carcass, and the more completely it does so the better will be the meat, say our English pork-butchers, but those of some parts of the Continent disagree with them, probably because there the pig's flesh is eaten for the most part fresh, or spiced, or cooked in other savoury modes, and but seldom pickled or dried, therefore the superabundance of blood in it communicates to it a juicy richness agreeable to their palates.

Mr. Waterton gives a very graphic description of the slaughter-house for swine at Rome, and the proceedings of the pig-killers:—

“As you enter Rome at the Porta del Popolo a little on your right is the great slaughter-house, with a fine stream of water running through it. It is, probably, inferior to none in Italy for an extensive plan and for judicious arrangements. Here some 700 or 800 pigs are killed on every Friday during the winter season. Nothing can exceed the dexterity with which they are despatched. About 30 of these large and fat black pigs are driven into a commodious pen, followed by three or four men, each with a sharp skewer in his hand, bent at one end, in order that it may be used with advantage. On entering the pen, these performers, who put you vastly in mind of assassins, make a rush at the hogs, each seizing one by the leg, amid a general yell of horror on the part of the victims. Whilst the hog and the man are struggling on the ground, the latter with the rapidity of thought pushes his skewer betwixt the fore-leg and the body quite into the heart, and then gives it a turn or two. The pig can rise no more, but screams for a minute or so and then expires. This process is continued until they are all despatched, the brutes sometimes rolling over the butchers, and sometimes the butchers over the brutes, with a yelling enough to stun one's ears. In the mean time the screams become fainter and fainter, and then all is silence on the death of the last pig. A cart is in attendance; the carcasses are lifted into it, and it proceeds through the street, leaving one or more dead hogs at the different pork-shops. No blood appears outwardly, nor is the internal hæmorrhage prejudicial to the meat, for Rome cannot be surprised in the flavour of her bacon or in the soundness of her hams.”*

* Waterton's Essays on Natural History.

PREPARING THE DEAD FIG.

As soon as the hog is dead, if it is intended for pork let it be laid on a board or table, and scalded with water nearly but not quite on the boil, and well scraped to get off all the hair and bristles. Bacon hogs may be singed by enveloping the body in straw and setting the straw on fire, and then scraping it all over; but when this is done care must be taken not to burn or parch the cuticle. The next thing to be done is to take out the entrails and well wash the interior of the body with luke-warm water so as to remove all blood and impurities, and afterwards dry it with a clean cloth; the carcass should then be hung up in a cool place for eighteen or twenty hours to become set and firm.

On the following day the feet are first of all cut off, so that they shall not disfigure the hams or hands, and plenty of knuckle shall be left to hang them up by; the knife is then inserted at the nape of the neck and the carcass divided up the middle of the back bone; the head is then separated from each side close behind the ears, and the hams and shoulders taken off and trimmed; some take out the chine and upper part of the ribs in the first place, but almost every locality has its peculiar way of proceeding.

PICKLING PORK.

For pickling pork the sides should be rubbed over with sugar and salt, and then laid in a brine-tub, in which a thick layer of salt has already been strewn, and a slighter one of sugar; the pork must be cut into such pieces as will admit of its lying quite flat in the tub; the rind must be placed downwards, and between each layer of pork a layer of salt and sugar. When the tub is quite full a layer of salt sufficiently thick to exclude the air must be spread over the whole, and the tub covered closely up and left for a week or ten days; if by this time the brine has not begun to rise, warm water should be sprinkled over the top layer.

Pork pickled in this way will be ready for use in about three months, and with proper care will be as good at the end of two years as it was when first begun. The sugar is considered to impart a finer and richer flavour than saltpetre, although the latter is most commonly used. There is no reason why both sugar and saltpetre may not be advantageously combined with the salt in pickling pork as well as in salting beef, for in this latter process there can be no question that a pickle composed of three parts salt, one part saltpetre, and one sugar, is the very best that can be used, making the meat tender, juicy, well flavoured, and fine coloured.

CURING BACON.

Bacon is the next form in which we eat pig's flesh. There has been some dispute as to the derivation of this word; some authors have suggested that it may be a corruption of the Scotch *baken* (dried), while others suggest that it is derived from *beechen*, as the finest fitches were considered to be those furnished by animals that were fattened on the fruit of the beech-tree, and this opinion is borne out by the fact that in the old Lancashire dialect the word bacon is both spelt and pronounced

beecken. A bacon hog will in general be fit for killing at about a twelve-month old, when he will weigh some ten or twelve score : those persons who care most about the hams will find it answer their purpose best not to let the animals be too fat, or so fat as a bacon-hog, and after having taken off the hams to cut up the carcass for fresh or pickling pork.

There are various methods of curing bacon and hams practised in the different counties of England, as well as in Scotland, America, and the Continent. We will proceed to describe a few of the best and most successful.

In Hampshire and Berkshire the practice is to choose a dry day, when the wind is blowing from the north, and kill the hog early in the morning (it having fasted the day before.) When dressed hang him up in some airy place for 24 hours, then proceed to cut him up. This being done, lay the flitches on the ground, and sprinkle them with salt lightly, so let them remain for six or eight hours ; then turn them up edgeways, and let the brine run off. In the mean time take two or three gallons of best salt, and two ounces of saltpetre, pounded very fine, and well-mixed together ; and the salting bench being made of the best seasoned oak, proceed to salt the flitches by rubbing in the salt on the back side of the flitch. This being done, turn the inside upwards, and lay on the salt about a quarter of an inch in thickness : in like manner treat every flitch. On the third day afterwards change the flitches, viz., take off the uppermost and reverse them, at the same time lay on salt a quarter of an inch in thickness. There will be no need of rubbing as before mentioned, neither should the saltpetre be repeated, otherwise the lean of the bacon will be hard. The changing and salting should be done every third day for six successive times, when the bacon will be sufficiently salt. Then proceed to rub off all the stale briny salt, and lay on each flitch a covering of clean fresh bran or sawdust, and take it to the drying-loft. It should be there hung by means of crooks fastened in the neck of the flitch, and remain for 14 or 16 days. The fuel most proper for drying bacon is cleft oak or ash, what is commonly called cord wood.

In Buckinghamshire, as soon as the flitches are cut from the hog they lay them on a form or table in a slanting position, and, supposing the whole hog to have weighed 12 or 14 score, take a quarter of a pound of saltpetre, pounded very fine, and sprinkle it all over the flitches, rubbing it well into the shoulder parts especially ; they then suffer them to remain twelve hours, after which they should be rubbed dry, and in the mean time seven pounds of salt mixed with one pound and a quarter of coarse brown sugar put into a frying-pan and heated on a clear fire, stirring it well that it may all be of the same temperature. This mixture, as hot as the hand can possibly bear it, may now be rubbed well into the flitches, which are then put one upon the other and laid in a salting pan or other contrivance, in order that the brine may form and be kept from wasting. The bacon must be kept in this situation four weeks, turning it and basting it well with the brine twice or thrice a week. At the expiration of this time take it from the brine, hang it up to dry, and smoke it, if preferred, which in the absence of a regular smokehouse may be done as follows :—Hang up the bacon in a chimney or other orifice, then underneath put down a

layer of dry straw, upon this a layer of mixed shavings, keeping out those from deal or fir, next a good layer of sawdust and some juniper-berries, or branches where procurable, and over all a mantle of wet straw or litter, which makes the fire give out much smoke without burning away too rapidly. This smoking must be repeated three or four times, or till the bacon appears thoroughly dry, when it may be hung up in the kitchen, or any dry place convenient.

In Kent the hog is *swaled* or singed, in preference to scalding and scraping the skin, as this latter process, it is considered, tends to soften the rind and injure the firmness of the flesh. The flitches are rubbed with dry salt and saltpetre in the proportion of one-third of the latter to two of the former, and laid in a trough, and there each one sprinkled over with this mixture. Here they continue for three weeks or a month, according to their size, during which time they are taken out once in two or three days and well rubbed with the brine and turned.

They are dried before a slow fire, and this process occupies about the same time that the salting has done. When it is completed the flitches are either hung up in a dry place, or deposited on stone slabs until wanted for domestic use.

In Somersetshire and Wiltshire the following is the common process:—

When the hogs are prepared the sides are first laid in large wooden troughs and sprinkled over with rock salt, and there left unmoved for four-and-twenty hours in order to let all the blood and other superfluous juices be completely drained off from them.

After this they are taken up and thoroughly wiped, and some fresh bay-salt, previously heated in an iron frying-pan, is rubbed into the flesh until it has absorbed a sufficient quantity. This rubbing is continued for four successive days, during which the flitches are usually turned every second day. Where the large hogs are killed it becomes necessary to keep the flitches in brine for three weeks, and after that interval to torn them out and dry them in the common manner.

In the county of Westmoreland, which is celebrated for the flavour of its hams, the following method prevails:—First they are thoroughly rubbed, usually with bay-salt alone, after which some curers advise that they shall be closely covered up, while others leave them on a stone for the purpose of draining off the brine. At the expiration of five days this friction is repeated with equal diligence, but the bay-salt is then combined with somewhat more than an ounce of saltpetre to each ham. They are next suffered to lie about a week either in hogsheads among the brine, or on stone benches, after which they are hung up in the chimney to dry. In this last part of the process there is a difference of practice. By some they are suspended so that they shall be dried solely by the heat arising from the fire below, without being exposed at all to the smoke, while by others they are hung up in the midst of the smoke, whether this arises from coals or peat.

In Yorkshire, after the pig has been killed, it is allowed to hang twenty-four hours previous to being cut up; one pound of saltpetre is then rubbed into a twenty-stone pig (of fourteen pounds to the stone,) and one and a half or two stones of common salt, taking care that it is well rubbed in; it is then put into a tub kept for the purpose. After having lain a fortnight it is turned over, and a little more salt applied

—say half a stone; it then remains a fortnight longer in the pickle-tub; whence it is taken and hung up in the kitchen, where it remains two months to dry, but should the winter be far advanced, and dry weather set in, a shorter period might suffice. After being taken from the top of the kitchen, the inside is washed over with quicklime and water to preserve it from the fly; it is then removed into a room not used by the family, away from heat, and where it will be kept perfectly dry and is ready for use at pleasure. The smoking system is rarely adopted.

Mr. Henderson, in his "Treatise on Swine," gives the following account of the mode of curing bacon and hams in Scotland:—

"In killing a number of swine, what sides you may have dressed the first day lay upon some flags or boards, piling them across each other, and giving each flitch a powdering of saltpetre, and then covering it with salt. Proceed in the same manner with the hams themselves, and do not omit giving them a little saltpetre, as it opens the pores of the flesh to receive the salt, and besides gives the ham a pleasant flavour, and makes it more juicy. Let them lie in this state about a week, then turn those on the top undermost, giving them a fresh salting. After lying two or three weeks longer, they may be hung up to dry in some chimney or smoke-house. Or, if the curer chooses, he may turn them over again, without giving them any more salt; in which state they may lie for a month or two, without catching any harm, until he has convenience for drying them. I practised for many years the custom of carting my flitches and hams through the country to farm-houses, and used to hang them in their chimneys, and other parts of the house, to dry, some seasons to the amount of five hundred carcasses. This plan I soon found was attended by a number of inconveniences, yet it is still common in Dumfriesshire.

"About twenty years ago I contrived a small smoke-house of a very simple construction. It is about twelve feet square, and the walls about seven feet high. One of these huts requires six joists across, one close to each wall, the other four laid asunder at proper distances. To receive five rows of flitches, they must be laid on the top of the wall. A piece of wood, strong enough to bear the weight of one flitch of bacon, must be fixed across the belly end of the flitch by two strings, as the neck end must hang downwards. The piece of wood must be longer than the flitch is wide, so that each end may rest upon a beam. They may be put so near to each other as not to touch. The width of it will hold twenty-four flitches in a row, and there will be five rows, which will contain one hundred and twenty flitches. As many hams may be hung at the same time above the flitches, contrived in the best manner one can. The lower end of the flitches will be within two and a half or three feet of the floor, which must be covered five or six inches thick with sawdust, which must be kindled at two different sides. It will burn, but not cause any flame to injure the bacon. The door must be kept close, and the hut must have a small hole in the roof, so that part of the smoke may ascend. That lot of bacon and hams will be ready to pack up in a hogshead, to send off, in eight or ten days, or a little longer if required, with very little loss of weight. After the bacon is salted, it may lie in the salt-house, as described, until an order is received.

"I found the smoke-house to be a great saving, not only in the ex-

pense and trouble of employing men to cart and hang it through the country, but it did not lose nearly so much weight by this process. It may be remarked, that whatever is shipped for the London market, or any other, both bacon and hams, must be knocked hard, and packed into a sugar hogshead, or something similar, to hold about ten hundred-weight. Bacon can only be cured from the middle of September until the middle of April."

The annexed system is the one usually pursued in Westphalia :—

"Six pounds of rock salt, two pounds of powdered loaf sugar, three ounces of saltpetre, and three gallons of spring or pure water, are boiled together. This should be skimmed when boiling, and when quite cold poured over the meat, every part of which must be covered with this brine. Small pork will be sufficiently cured in four or five days; hams, intended for drying, will be cured in four or five weeks, unless they are very large. This pickle may be used again and again, if it is fresh boiled up each time with a small addition to the ingredients. Before, however, putting the meat into the brine, it must be washed in water, the blood pressed out, and the whole wiped clean.

"Pickling-tubs should be larger at the bottom than at the top, by which means, when well packed, the pork will retain its place until the last layer is exhausted. When the pork is cool it may be cut up, the hams and shoulders reserved for bacon, and the remainder salted. The bottom of the tub or barrel should be covered with rock salt, and on it a layer of meat placed, and so on until the tub is filled. The salt should be used liberally, and the barrel filled with strong brine boiled and skimmed, and then cooled.

"The goodness and preservation of hams and shoulders depends on their smoking as well as their salting. Owing to some misconstruction of the smoke-house, and to the surface of the meat not being properly freed from saline matter, or other causes, it not unfrequently happens that during the process of smoking, the meat is constantly moist, and imbibes a pyroligneous acid taste and smell, destructive of its good qualities.

"The requisites of a smoke-house are, that it should be perfectly dry; not warmed by the fire that makes the smoke; so far from the fire, that any vapour thrown off in the smoke may be condensed before reaching the meat; so close as to exclude all flies, mice, &c., and yet capable of ventilation and admitting the escape of smoke.

"The Westphalian hams, the most celebrated in Europe, are principally cured at and exported from Hamburg. The smoking of these is performed in extensive chambers, in the upper stories of high buildings. Some are four or five stories high, and the smoke is conveyed to these rooms from fires in the cellar through tubes, on which the vapour is condensed and the heat absorbed, so that the smoke is both dry and cool when it comes in contact with the meat. They are thus kept perfectly dry, and acquire a colour and flavour unknown to those smoked in the common method.

"Hams after being smoked may be kept any length of time by being packed in dry ashes or powdered charcoal, or by being kept in the smoke-house if that is secure against theft, or a smoke is made under them once a-week. When meat is fully smoked or dried, it may be kept hung up in any dry room by slipping over it a cotton bag, the

neck of which is closely tied around the string that supports the meat, and thus excludes the bacon-bug, fly, &c. The small part of a ham or shoulder should always be hung downward in the process of smoking, or when suspended for preservation."*

The following method of curing bacon—which has been practised in Virginia and Kentucky by one person with perfect success for five-and-thirty years, during which time he states that he has cured on the average from six to eight thousand pounds every year, or, in the whole, the enormous quantity of from a hundred to a hundred and twenty-five tons—will conclude what we have to say on this division of our subject.

"The hogs should be killed when the weather is sufficiently cold to ensure that when they are hung up, after having been cleaned, they shall not only become quite cold to the touch, but feel hard and stiff. They should be killed on one day, and cut up and salted on the next. When the weather is very cold they should be hung in a cellar or somewhere where they are not likely to become frozen, but if there be no danger of this let them hang in the open air.

"The process of cutting up is too well known to need description; nothing further need be said than that the backbone or chine should be taken out, as also the spare-ribs from the shoulders, and the mouse-pieces and short-ribs or griskins from the middlings. No acute angles should be left to shoulders or hams. In salting up in Virginia, all the meat except the heads, jowls, chins, and smaller pieces, is put into *powdering-tubs* (water-tight half-hogsheads). In Kentucky, large troughs, ten feet long and three or four feet wide at the top, made of the *Liriodendron tulipifera*, or poplar-tree, are used. These are much the most convenient for packing the meat in, and are easily caulked if they should crack so as to leak. The salting-tray, or box in which the meat is to be salted, piece by piece, and from which each piece, as it is salted, is to be transferred to the powdering-tub or trough, must be placed just so near the trough that the man standing between can transfer the piece from one to the other easily, and without wasting the salt as they are lifted from the salting-box into the trough. The salter stands on the off-side of the salting-box. Salt the hams first, the shoulders next, and the middlings last, which may be piled up two feet above the top of the trough or tub. The joints will thus in a short time be immersed in brine.

"Measure into your salting-tray four measures of salt (a peck measure will be found most convenient,) and one measure of clean dry sifted ashes; mix and incorporate them well. The salter takes a ham into the tray, rubs the skin with this composition and the raw hock end, turns it over, and packs the composition of salt and ashes on the fleshy side till it is at least three-quarters of an inch deep all over it, and on the interior lower part of the ham, which is covered with the skin, as much as will lay on it. The man who stands ready to transfer the pieces as they are salted takes up the piece, and deposits it carefully, without displacing the composition, with the skin side down, in the bottom of the trough. Each succeeding ham is thus deposited side by side, so as to leave the least possible space unoccupied.

* Albany Cultivator.

“When the bottom is all covered, see that every visible part of this layer of meat is covered with the composition of salt and ashes. Then begin another layer, every piece being covered on the upper or fleshy side three-quarters of an inch thick with the composition. When your trough is filled even full in this way with the joints, salt the middlings with salt only, without the ashes, and pile them up on the joints so that the liquified salt may pass from them into the trough. Heads, jowls, backbones, &c., receive salt only, and should not be put in the trough with the large pieces.

“Much slighter salting will preserve them if they are salted upon loose boards, so that the bloody brine from them can pass off. The joints and middlings are to remain in and above the trough without being re-handled, re-salted, or disturbed in any way, till they are to be hung up to be smoked.

“If the hogs weighed not more than 150 lbs., the joints need not remain longer than five weeks in the pickle; if they weighed 200 or upwards, six or seven weeks is not too long. It is better that they should stay in too long rather than too short a time.

“In three weeks, jowls, &c., may be hung up. Taking out of pickle, and preparation for hanging up to smoke, is thus performed:—Scrape off the undissolved salt (and if you had put on as much as directed, there will be a considerable quantity on all the pieces not immersed in the brine; this salt and the brine is all saved; the brine boiled down, and the dry composition given to stock, especially to hogs.) Wash every piece in lukewarm water, and with a rough towel clean off the salt and ashes. Then put the strings in to hang up. Set the pieces up edgewise, that they may drain and dry. Every piece is then to be dipped into the *meat-paint*, and hung up to smoke. The *meat-paint* is made of warm, not hot, water and very fine ashes stirred together until they are of the consistence of thick paint. When they are dipped in this, they receive a coating which protects them from the fly, prevents dripping, and tends to lessen all external injurious influences. Hang up the pieces while yet moist with the paint, and smoke them well.”

POISONOUS PROPERTIES OF BRINE.

It is a fact worthy of notice that the brine in which pork or bacon has been pickled is poisonous to pigs. Several cases are on record in which these animals have died in consequence of a small quantity of brine having been mingled with the wash, under the mistaken impression that it would answer the same purpose and be equally as beneficial as in the admixture of a small quantity of salt.

IMPORTATION OF BACON, HAM, AND SALTED PORK.

From a reference to the accounts furnished by the Board of Trade, it appears that there have been imported during the last three years,—

	1844.	1845.	1846.
BACON cwts.	36	51	2,768
HAMS "	6,732	5,462	11,252
PORK, Salted :—			
Of British Possessions "	2,153	1,517	} 72,519
Foreign "	28,627	38,128	
Fresh "	63	133	133
Total of Pork "	30,843	39,878	72,652

And of these three articles there were entered for home consumption,—

	1844.	1845.	1846.
BACON cwts.	36	54	2,768
HAMS "	3,568	2,603	8,385
PORK, Salted :—			
Of British Possessions "	248	172	} 72,519
Foreign "	1,073	1,289	
Fresh "	63	133	133
Total of Pork "	1,384	1,594	72,652

These tables demonstrate the enormous increase in the importation of these staple articles of food which has taken place since the abolition of the Tariff of 1842 and the substitution of the new one. The alteration of duties is as follows :—

	In 1842.	New Tariff.
	s. d.	s. d.
On Bacon from Foreign Countries	14 0 per cwt.	7 0 per cwt.
British possessions	3 6 "	2 0 "
Ham from Foreign Countries	14 0 "	7 0 "
British Possessions	3 6 "	2 0 "
Salted Pork from Foreign Countries	8 0 "	0 0 "
British Possessions	2 0 "	0 0 "

Previous to 1842 the duty on bacon and ham amounted to 28s. and 7s. per cwt., and that on pork to 16s. and 4s.; swine were then prohibited; but when, by the Act 5 & 6 Vict. cap. 47, they became admissible, there were imported,—

In 1842.	In 1843.	In 1844.	In 1845.	In 1846.
<u>415</u>	<u>361</u>	<u>269</u>	<u>1,598</u>	<u>3,443</u>

Here again we find the same wonderful increase. In 1845 seven times the number are imported that were brought over in 1844; and in 1846 the import of 1845 is doubled. Yet there is no diminution created in the provision trade by this extraordinary increase in that of live animals, but, on the contrary, it too increases in 1845, and is again doubled in 1846. And the increase of demand is proportionate with that of the supplies.

The accounts of one branch of our imports will this present year, however, in all probability, show a material defalcation in the amount; we allude to those arising from Ireland, whence a large number of the pigs which come to our markets are supplied, and where the present state of derth has caused numbers of these animals to be destroyed. This fact ought to stimulate our native breeders to increased exertions. In from 1820 to 1825 there was on the average from 204,380 to 338,218 cwt. of bacon and hams imported yearly into England from the sister country. Since the last-named period there has been no decrease; but, the trade between Ireland and Great Britain having been placed on the footing of a coasting-trade, and these articles having been imported without specific duties, it is not so easy to ascertain the precise amounts brought over; they may be, however, estimated at about 500,000 cwt. per annum.

The keeping of swine is fast becoming something more than a mere means of disposing of offal and matters which would otherwise be wasted; and we trust that the value and lucrativeness of this branch of rural economy will soon be fully acknowledged, and that swine will be duly estimated among farmers and breeders. The next step must of necessity speedily follow: men of science will no longer deem them beneath their notice; their habits, instincts, and ailments will be properly studied; individuals as well as the world will be benefited; and a new and important field of knowledge thrown open.

Yet another source of profit accruing from swine, and we close this chapter.

PIG'S DUNG AS MANURE.

The manure proceeding from the pigsty has been often much undervalued, and for this reason,—that the litter has been considered as forming the principal portion of it, whereas it constitutes the least valuable part; and, indeed, where all due attention is paid to the cleanliness of the animals and of their dwellings, it can scarcely be regarded as manure at all, at least by itself.

It is the urine and the dung which are valuable; and these are now generally allowed to be peculiarly so, and to constitute no inconsiderable items in the profits arising from the keeping of swine. These matters are, from the very nature of the food of the animals, exceedingly

rich and oleaginous, and materially benefit cold soils and grass-lands. But, as with most other things relative to swine, this has also been too much neglected ; the animals have been suffered to wander about at will, voiding their dung and urine in waste ; or, when confined, the sty perhaps furnished no means of collecting and saving it. We will venture to prophesy that the partial alteration of system which is now gradually spreading will speedily lead to amendment in this point also ; and the dung from the piggery will be husbanded with a care little inferior to that bestowed on the fold, stable, or cow-house dung.

CHAPTER XV.

The Medicines used in combating the Maladies of Swine.

THE medicines generally used in the treatment of swine are neither numerous nor complicated. There are, doubtless, many others, besides those enumerated in the following list, which might be employed with advantage, and which will, as the diseases of these domesticated animals become more studied, be discovered and made use of.

The caution requisite in the administration of all medicines has been already alluded to in Chapter X.; force should as seldom as possible be had recourse to.

It must be borne in mind that the doses here given are taken on the average, and must always be proportioned to the size, and constitution, and state of health of the animal. In all cases of actual disease, the best and most economical plan will be to have recourse to some good veterinary surgeon within reach. The life of many a valuable animal will thus be saved, for the mere amateur in surgery is always liable to blunder in the choice of remedies, as well as in the application of them, and will often create evils far greater than those he is endeavouring to cure.

ANTIMONY.—Seldom given by itself. In conjunction with sulphur, forms an efficient cooling and cleansing medicine; and with sulphur and hog's lard, or palm or train-oil, constitutes the common mange-ointment.

ARSENIC.—Useful in mange, and other cases of diseases of the skin. From one ounce to an ounce and a half, dissolved in a gallon of water, will form a solution of sufficient strength.

CALOMEL.—A dangerous drug, and one better left alone. In cases of emergency, however, it may be given in conjunction with an equal portion of tartarized antimony. From two to three grains of each will constitute an active emetic.

CREOSOTE.—Useful in cases of virulent cutaneous eruptions.

CROTON OIL.—A powerful purgative, and one that should only be had recourse to in cases of obstinate constipation. From one to three drops may be given.

DIGITALIS.—A valuable sedative medicine in cases of fever.

EPSOM SALTS.—A very useful and efficient purgative, suitable to most cases of common occurrence. From half an ounce to an ounce and a half may be ordinarily given.

GENTIAN.—An excellent stomachic; every aperient draught should contain a portion of this or the next-mentioned matter.

GINGER.—Also a good stomachic, and a tonic as well. From three scruples to a drachm and a half may be given of this and the preceding drug.

LINSEED OIL.—Valuable as an occasional purgative, especially where there is much intestinal inflammation.

MERCURIAL OINTMENT.—Used for mange and scabs, in conjunction with the sulphur ointment. The proportions are one part of the former to eight parts of the latter.

NITRE.—An excellent cooling medicine in all cases where there is tendency to fever. From one to two drachms may be given dissolved in the water the animal drinks.

PALM OIL.—The best emollient to form the basis of all ointments for cutaneous eruptions.

SALT.—A valuable adjunct in purifying the blood, and maintaining the animals in good condition. A small quantity should be regularly mingled with the food.

SULPHUR.—A good cooling medicine, and the best gentle aperient for ordinary use we have. It also constitutes the chief ingredient in mange-ointment.

TARTAR EMETIC.—Useful as an emetic.

VINEGAR.—Valuable in all cases requiring cooling fomentations.

TOBACCO.—A decoction of this plant efficacious and soothing in cases of mange and cutaneous eruptions, especially when mingled with equal parts of digitalis.

TURPENTINE.—A destructive agent in cases of worms: it may be given to swine without danger.

INDEX.

- ABORTION**, treatment of, 125.
Abstinence from pork, necessary in hot climates, 13.
Acorns, pigs thrive on, 139, 140.
Age, great, of wild boars, 34.
Agricultural Societies, influence of, on breeding, 134.
Albert, Prince, his farm at Windsor, 66; gains a prize for pigs, 65.
America, importation of breeds of swine into, 47; six species of hogs in, 45; wild boars in, 44.
Analogy between the Chinese and their pigs, 51.
Anatomy of swine, 75, &c.
Ancients, boar-hunts of, 36, 37.
Anecdotes of pigs, 25, 26, 27, 28, 29, 30.
Anglo-Saxons, boar-hunts of, 37.
Animal substances, feeding swine on, 144.
Apoplexy in pigs, 81.
Apparatus for preparing pigs' food, 149.
Apple, swine, fed on, 140.
Ardennes, wild boar of, 39.
Armour, hogs in, or Tatous, 11.
Ashes given to pigs, 145.
Attachments of swine, 29.
Autumn, best time for fattening pigs, 145.
- B.**
- Babiroussa**, the, 10; at Zoological Gardens, 11.
Bacon, curing, 151; derivation of the word, 156; importation of, 163.
